Lecture 2: OS Concepts

Prof. Seyed Majid Zahedi

<https://ece.uwaterloo.ca/~smzahedi>

Outline

- Brief history of OS's
- Four fundamental OS concepts
 - Thread
 - Address space
 - Process
 - Dual-mode operation/protection

Very Brief History of OS

- Several distinct phases:
 - Hardware expensive, humans cheap
 - Eniac, ... Multics

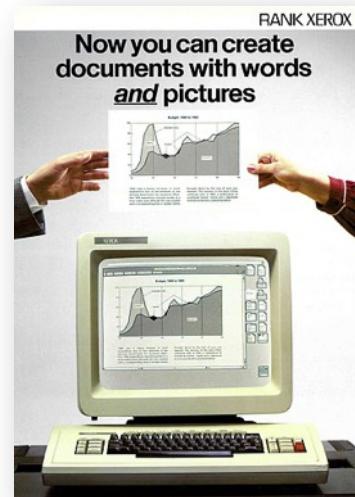

“I think there is a world market for maybe five computers.” – Thomas Watson, chairman of IBM, 1943

Thomas Watson was often called “the world's greatest salesman” by the time of his death in 1956

Very Brief History of OS

- Several distinct phases:
 - Hardware expensive, humans cheap
 - Eniac, ... Multics
 - Hardware cheaper, humans expensive
 - PCs, workstations, rise of GUIs
 - Hardware very cheap, humans very expensive
 - Ubiquitous devices, widespread networking

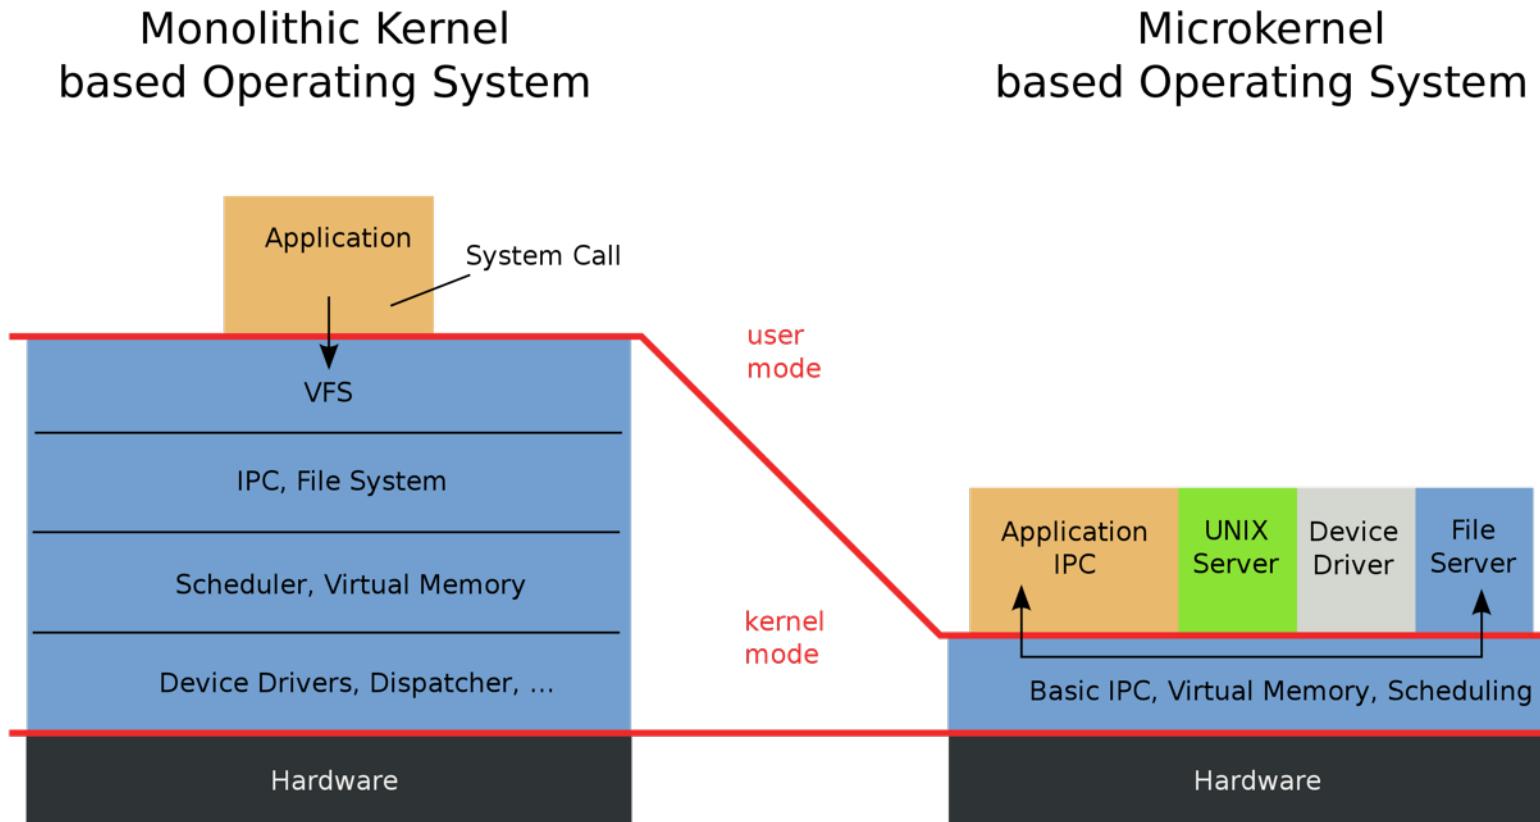

Very Brief History of OS

- Several distinct phases:
 - Hardware expensive, humans cheap
 - Eniac, ... Multics
 - Hardware cheaper, humans expensive
 - PCs, workstations, rise of GUIs
 - Hardware very cheap, humans very expensive
 - Ubiquitous devices, widespread networking
- Rapid change in hardware leads to changing OS
 - Batch \Rightarrow multiprogramming \Rightarrow timesharing \Rightarrow GUI \Rightarrow ubiquitous devices
 - Gradual migration of features into smaller machines
- Today
 - Small OS: 100K lines / Large: 20M lines (10M browser!)
 - 100-1000 people-years

OS Archaeology

- Due to high cost of building OS from scratch, most modern OS's have long lineage
- Multics \Rightarrow AT&T Unix \Rightarrow BSD Unix \Rightarrow Ultrix, SunOS, NetBSD,...
- Mach (micro-kernel) + BSD \Rightarrow NextStep \Rightarrow XNU \Rightarrow Apple OS X, iPhone iOS
- MINIX \Rightarrow Linux \Rightarrow Android, Chrome OS, RedHat, Ubuntu, Fedora, Debian, Suse,...
- CP/M \Rightarrow QDOS \Rightarrow MS-DOS \Rightarrow Windows 3.1 \Rightarrow NT \Rightarrow 95 \Rightarrow 98 \Rightarrow 2000 \Rightarrow XP \Rightarrow Vista \Rightarrow 7 \Rightarrow 8 \Rightarrow 10 \Rightarrow ...

Monolithic vs Microkernel OS

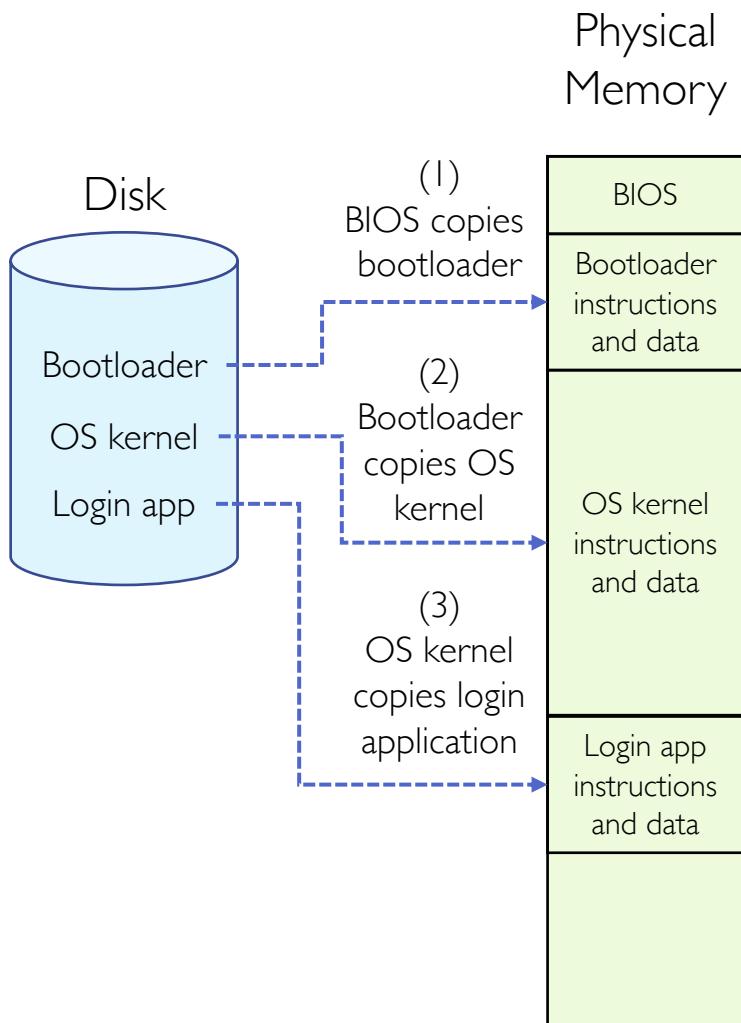

Influence of Microkernels

- Microkernels provide better modularity, security, and fault tolerance, but they introduce higher communication overhead
 - Too many context switches
- Many OSes provide some services externally, like microkernels
 - OS X and Linux: windowing (graphics and UI)
- Some currently monolithic OSes started as microkernels
 - Windows family originally had microkernel design
 - OS X is hybrid of Mach microkernel and FreeBSD monolithic kernel

Today: Four Fundamental OS Concepts

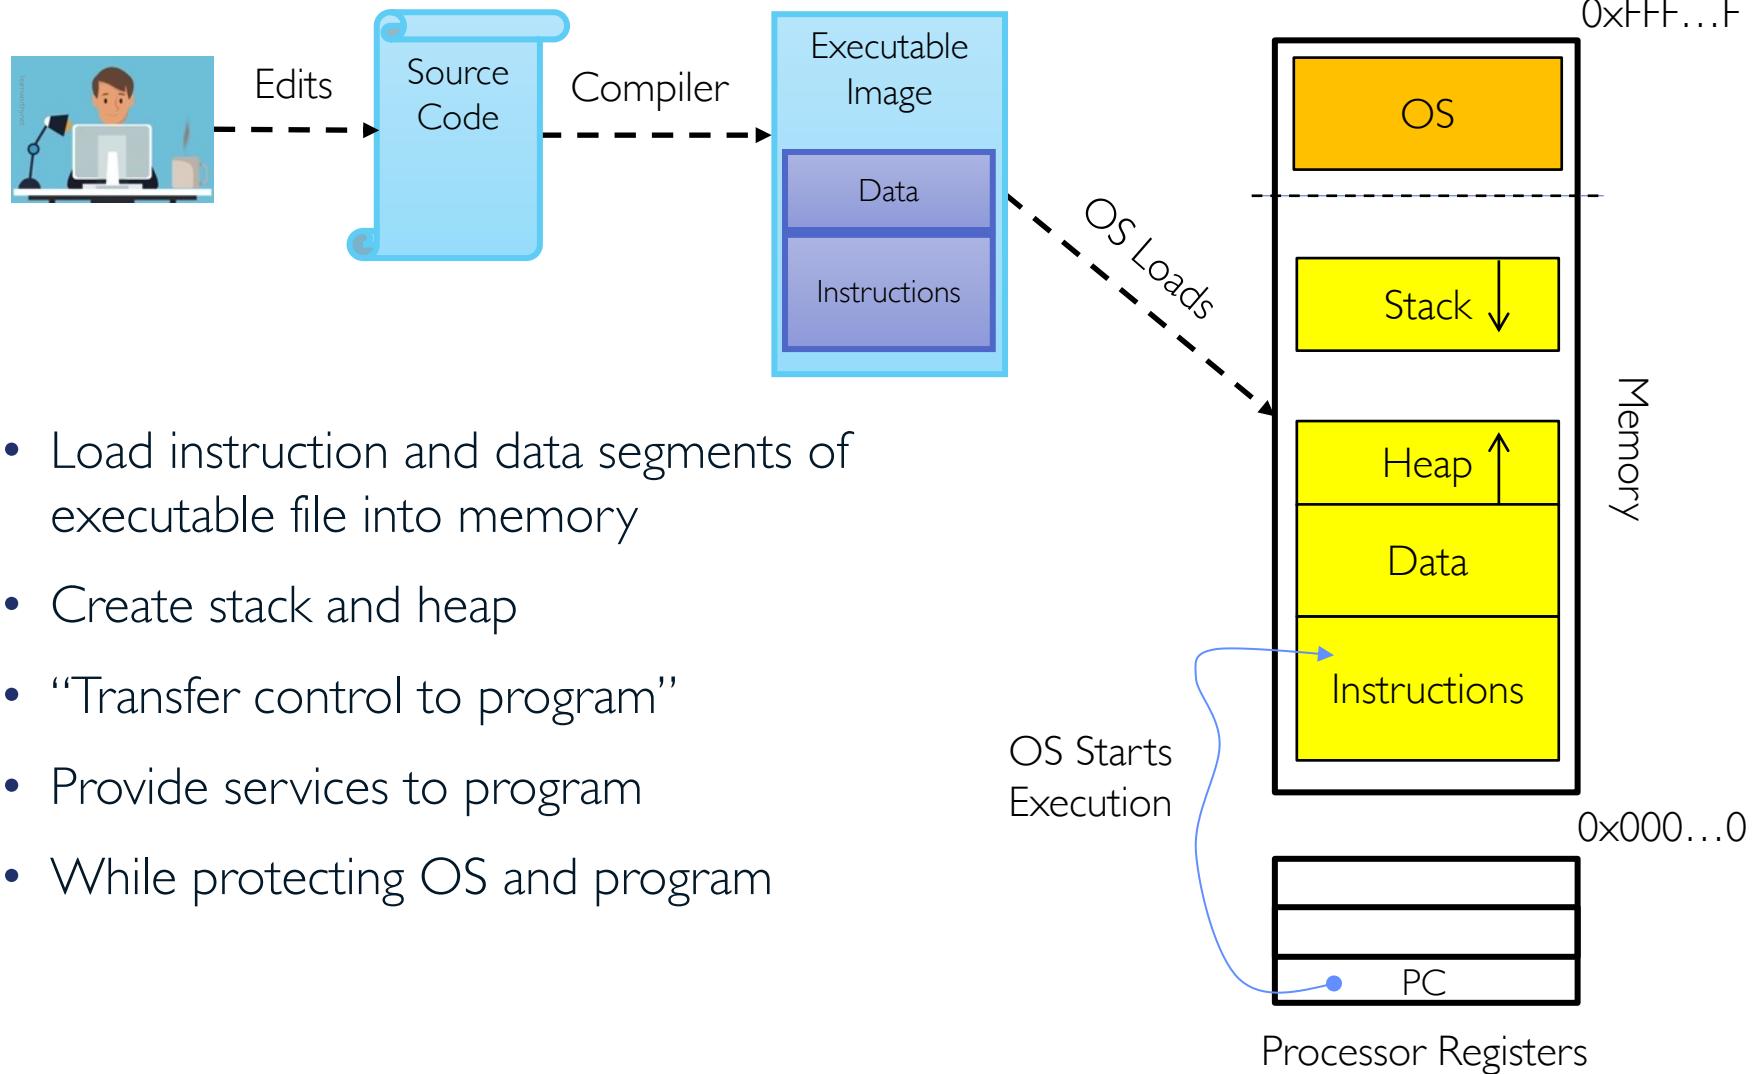

- Thread
 - Single unique execution context which fully describes program state
 - Program counter, registers, execution flags, stack
- Address space (with translation)
 - Address space which is distinct from machine's physical memory addresses
- Process
 - Instance of executing program consisting of address space and 1+ threads
- Dual-mode operation/protection
 - Only "system" can access certain resources
 - OS and hardware are protected from user programs
 - User programs are isolated from one another by controlling translation from program virtual addresses to machine physical addresses

Booting OS

- In most x86 systems, BIOS is stored on Boot ROM
 - Expensive and writing to it is slow
- Why not storing kernel on Boot ROM?
 - Hard to update (OS updates are frequent)
- Why does BIOS load bootloader not OS?
 - Might have multiple OSes installed
 - BIOS needs to read raw bytes from disk, whereas bootloader needs to know how to read from filesystem

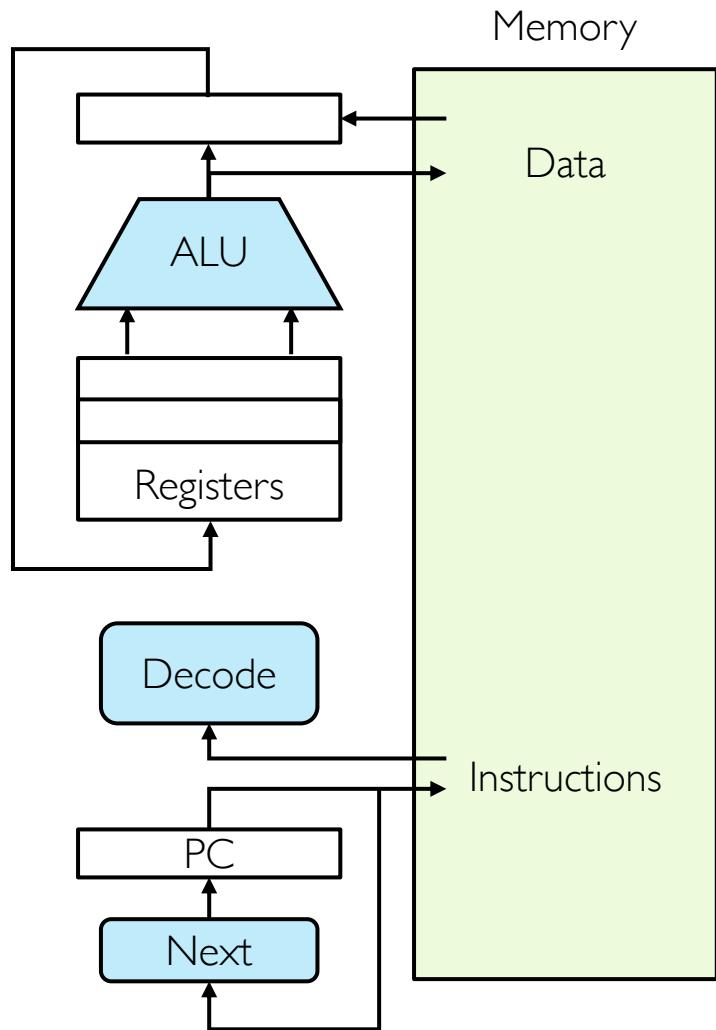

OS Bottom Line: Run Programs

Instruction Cycle: Fetch, Decode, Execute

- Execution sequence
 - Fetch instruction at PC
 - Decode
 - Execute (possibly using registers)
 - Write results to registers/memory
 - $PC \leftarrow Next(PC)$
 - Repeat

Next instruction or jump
to new address ...

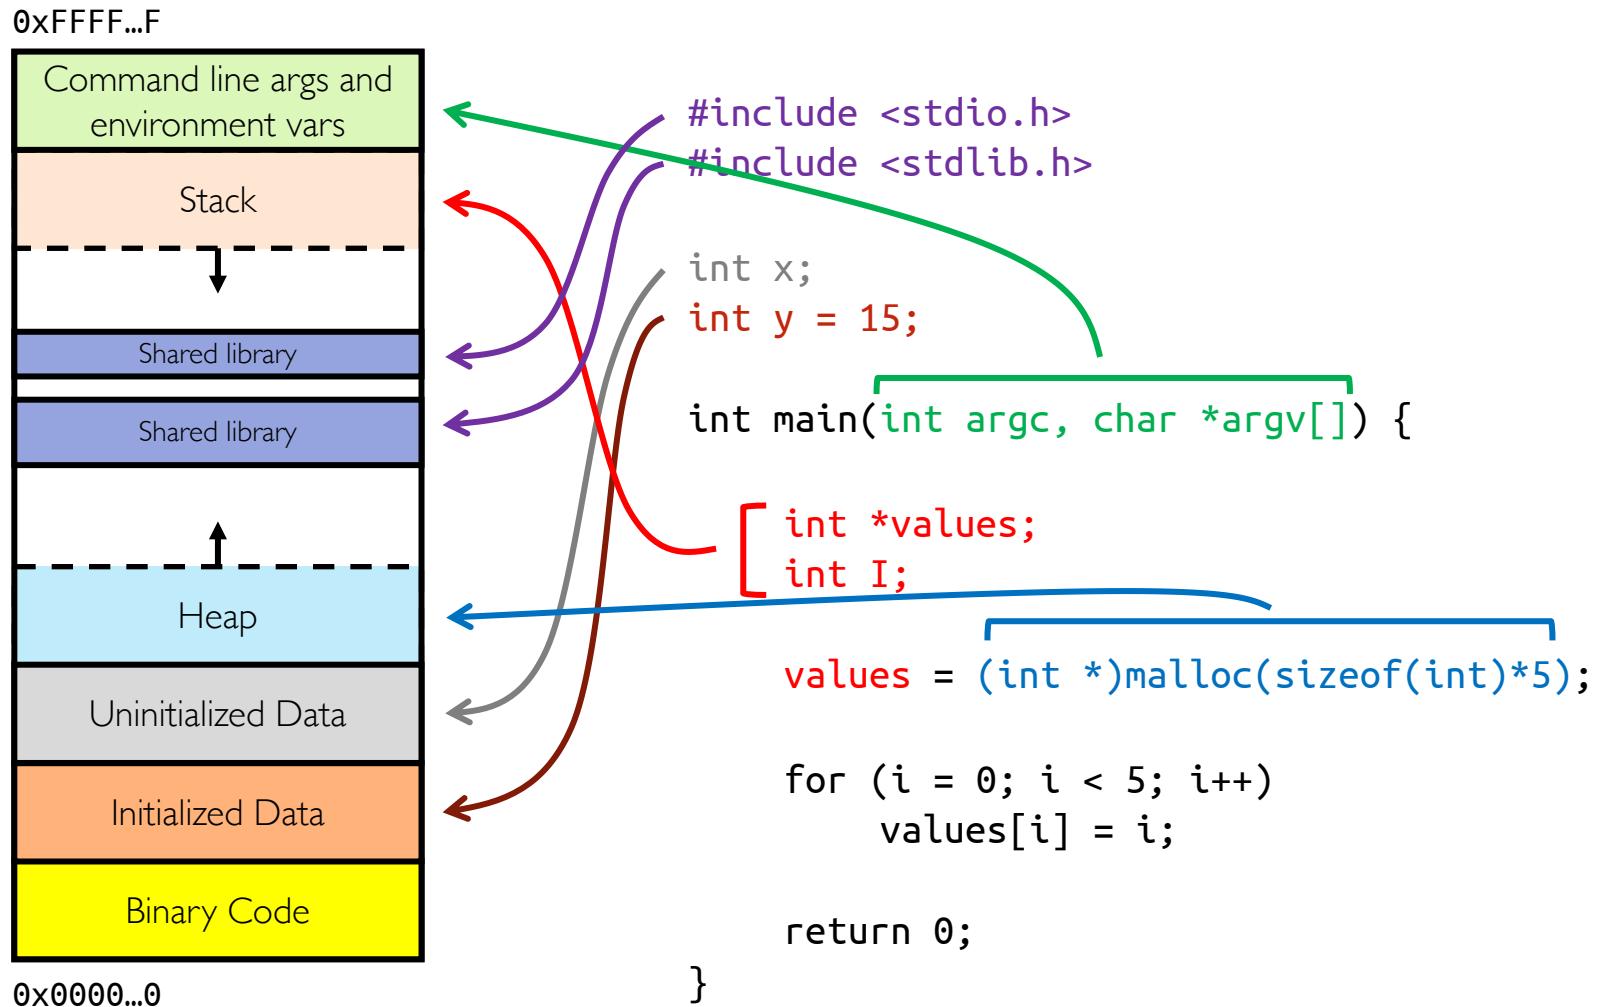

Thread (1st OS Concept)

- Thread is single **unique** execution context
 - Program counter (PC), registers, execution flags, stack
- Thread is executing on processor when it resides in processor's registers
- Registers hold root state of thread (the rest is "in memory")
- Registers are defined by **instruction set architecture (ISA)** or by compiler
 - Stack pointer (SP) holds address of top of stack
 - Other conventions: frame pointer, heap pointer, data
 - PC register holds the address of executing instruction in the thread

Address Space (2nd OS Concept)

- **Address space**: set of accessible addresses and their state
- **Physical memory**: data storage medium
- **Physical addresses**: addresses available on physical memory
 - For 4GB of memory: 2^{32} ~ 4 billion addresses
- **Virtual addresses**: addresses generated by program
 - For 64-bit processor: $2^{64} > 18$ quintillion (10^{18}) addresses

Virtual Address Space Layout of C Programs

Stack Example

```
A0: A(int tmp) {  
A1:     if (tmp<2)  
A2:         B();  
A3:         printf(tmp);  
A4:     }  
B0: B() {  
B1:     C();  
B2: }  
C0: C() {  
C1:     A(2);  
C2: }  
ext:  
      A(1);
```

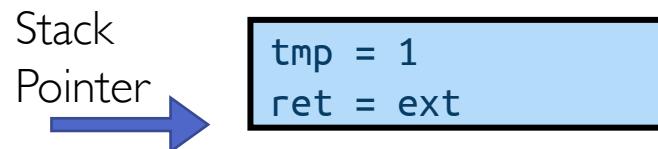

Stack
Pointer →

```
tmp = 1  
ret = ext
```

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Stack Example

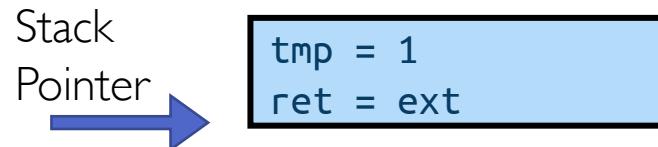

```
A0: A(int tmp) {  
A1:     if (tmp<2)  
A2:         B();  
A3:         printf(tmp);  
A4:     }  
B0: B() {  
B1:     C();  
B2: }  
C0: C() {  
C1:     A(2);  
C2: }  
        A(1);  
ext:
```

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Stack Example

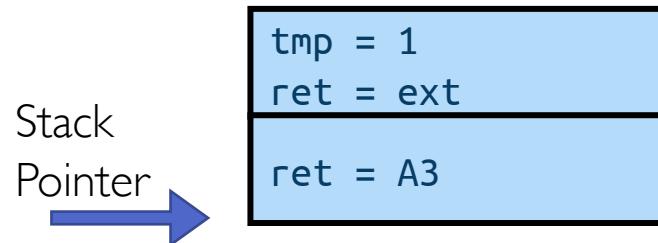

```
A0: A(int tmp) {  
A1:     if (tmp<2)  
A2:         B();  
A3:     printf(tmp);  
A4: }  
B0: B() {  
B1:     C();  
B2: }  
C0: C() {  
C1:     A(2);  
C2: }  
        A(1);  
ext:
```

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Stack Example

```
A0: A(int tmp) {  
A1:     if (tmp<2)  
A2:         B();  
A3:         printf(tmp);  
A4:     }  
B0: B() {  
B1:     C();  
B2: }  
C0: C() {  
C1:     A(2);  
C2: }  
        A(1);  
ext:
```

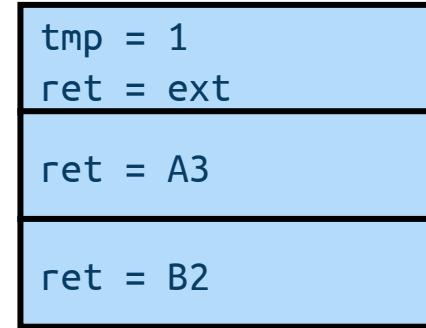

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Stack Example

```
A0: A(int tmp) {  
A1:     if (tmp<2)  
A2:         B();  
A3:         printf(tmp);  
A4:     }  
  
B0: B() {  
B1:     C();  
B2: }  
  
C0: C() {  
C1:     A(2);  
C2: }  
        A(1);  
  
ext:
```

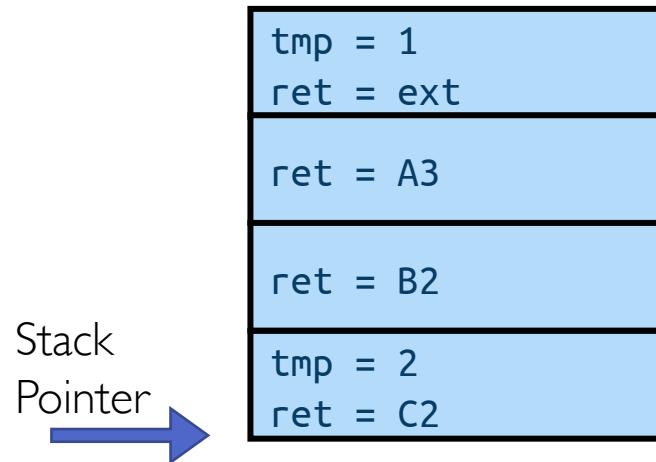

Stack
Pointer 

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Stack Example

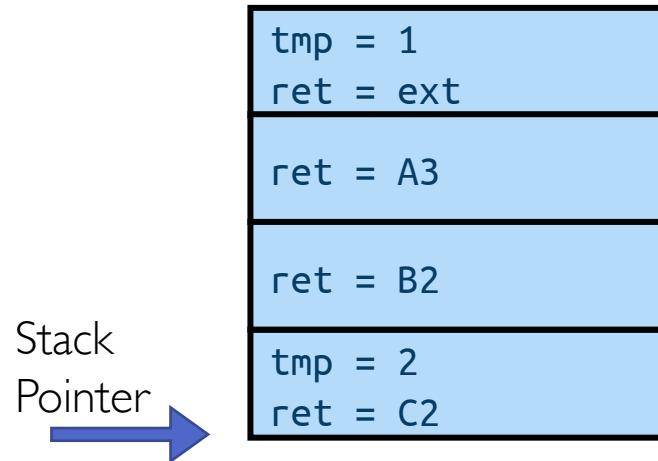

```
A0: A(int tmp) {  
A1:     if (tmp<2)  
A2:         B();  
A3:         printf(tmp);  
A4:     }  
B0: B() {  
B1:     C();  
B2: }  
C0: C() {  
C1:     A(2);  
C2: }  
        A(1);  
ext:
```

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Stack Example

```
A0: A(int tmp) {  
A1:     if (tmp<2)  
A2:         B();  
A3:     printf(tmp);  
A4: }  
B0: B() {  
B1:     C();  
B2: }  
C0: C() {  
C1:     A(2);  
C2: }  
        A(1);  
ext:
```

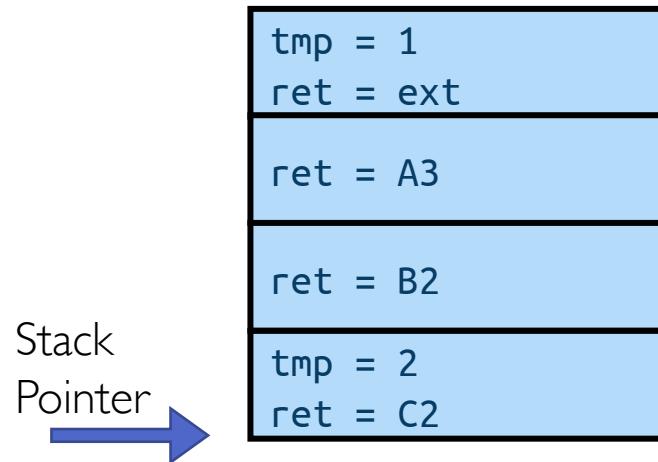

> 2

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Stack Example

```
A0: A(int tmp) {  
A1:     if (tmp<2)  
A2:         B();  
A3:         printf(tmp);  
A4:     }   
B0: B() {  
B1:     C();  
B2: }  
C0: C() {  
C1:     A(2);  
C2: }  
        A(1);  
ext:
```

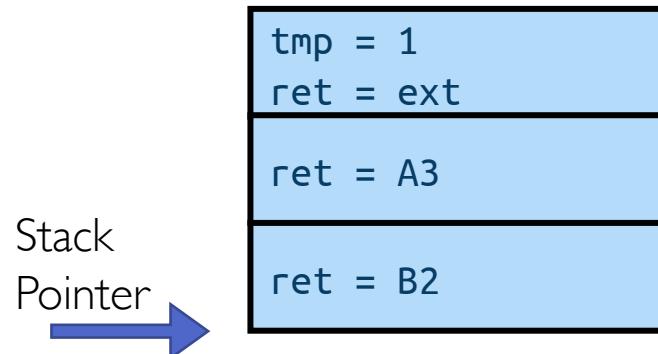

> 2

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Stack Example

```
A0: A(int tmp) {  
A1:     if (tmp<2)  
A2:         B();  
A3:         printf(tmp);  
A4:     }  
  
B0: B() {  
B1:     C();  
B2: }  
  
C0: C() {  
C1:     A(2);  
C2: }  
        A(1);  
  
ext:
```

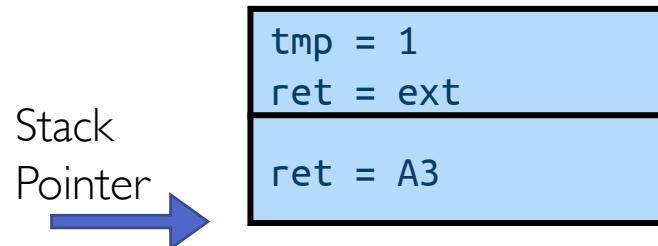

> 2

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Stack Example

```
A0: A(int tmp) {  
A1:     if (tmp<2)  
A2:         B();  
A3:         printf(tmp);  
A4:     }  
B0: B() {  
B1:     C();  
B2: }  
C0: C() {  
C1:     A(2);  
C2: }  
        A(1);  
ext:
```

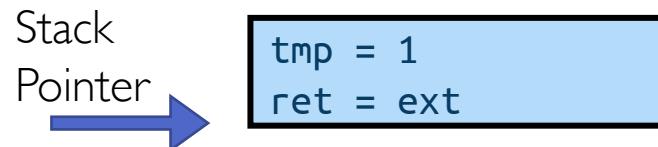

> 2

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Stack Example

```
A0: A(int tmp) {  
A1:     if (tmp<2)  
A2:         B();  
A3:         printf(tmp);  
A4:     }  
B0: B() {  
B1:     C();  
B2: }  
C0: C() {  
C1:     A(2);  
C2: }  
        A(1);  
ext:
```

> 21

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Stack Example

```
A0: A(int tmp) {  
A1:     if (tmp<2)  
A2:         B();  
A3:         printf(tmp);  
A4:     }   
B0: B() {  
B1:     C();  
B2: }  
C0: C() {  
C1:     A(2);  
C2: }  
        A(1);  
ext:
```

Stack
Pointer 

```
tmp = 1  
ret = ext
```

> 21

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

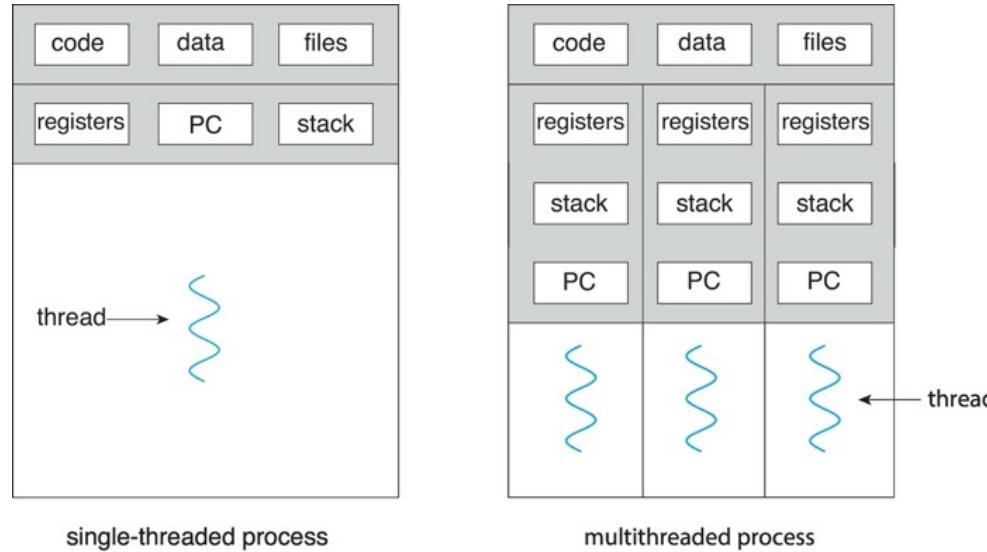

Stack Example

```
A0: A(int tmp) {  
A1:     if (tmp<2)  
A2:         B();  
A3:         printf(tmp);  
A4:     }  
B0: B() {  
B1:     C();  
B2: }  
C0: C() {  
C1:     A(2);  
C2: }  
        A(1);  
ext: 
```

> 21

- Stack holds temporary results
- Permits recursive execution
- Crucial to modern languages

Process (3rd OS Concept)

- Process: execution environment with **restricted rights**
 - Address space with one or more threads
 - Owns memory (address space)
 - Owns file descriptors, file system context, ...
- Fundamental tradeoff between **protection and efficiency**
 - Communication easier within a process
 - Communication harder between processes

What Does it Take to Create Process?

- Must construct new process control block (PCB)
 - Inexpensive
- Must set up new *page tables* for address space (more on this later)
 - More expensive
- Copy data from parent process? (Unix `fork()`)
 - With Unix `fork()`, child process gets copy of parent's memory and I/O state
 - Originally very expensive
 - Much less expensive with "copy on write" (more on this later)
- Copy I/O state (file handles, etc.)
 - Medium expense

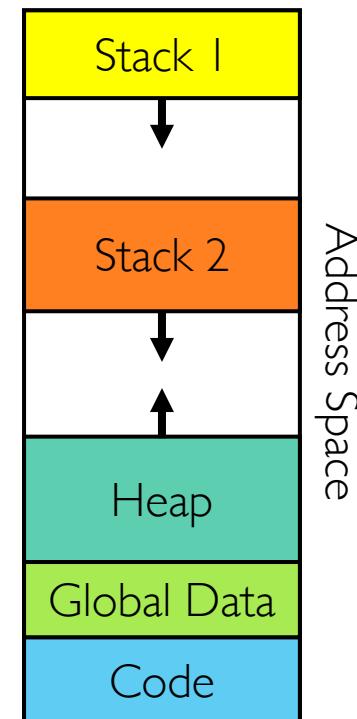

Multithreaded Processes

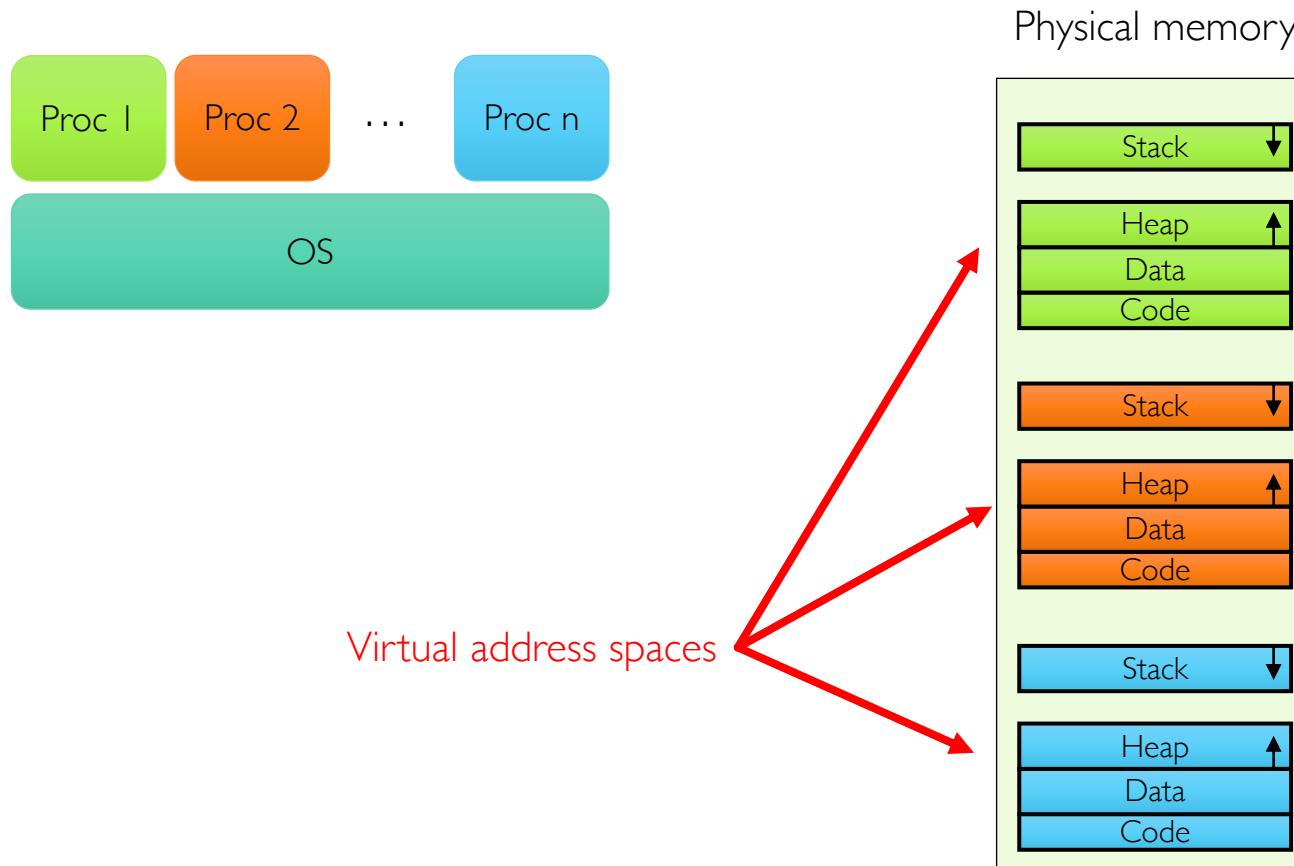

- Threads encapsulate **concurrency** and are **active** components
- Address spaces encapsulate **protection** and are **passive** part
 - Keeps buggy program from trashing system
- Why have multiple threads per address space?
 - Processes are expensive to start, switch between, and communicate between

Memory Footprint of Multiple Threads

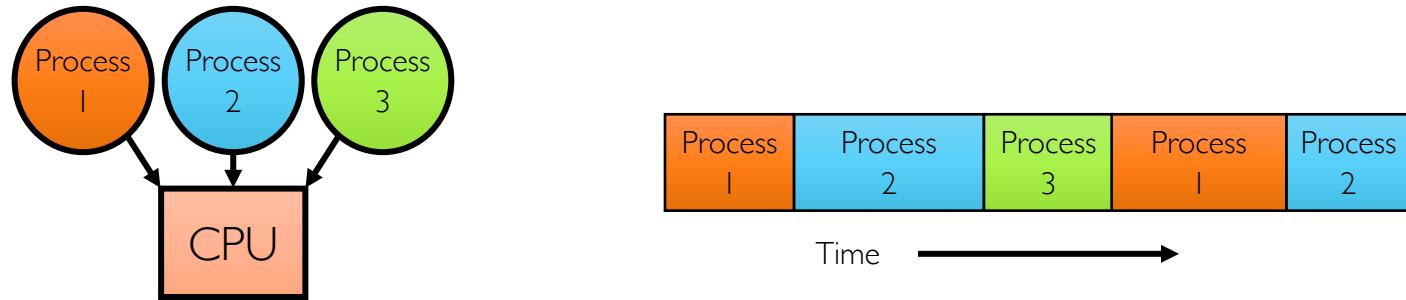

- How do we position stacks relative to each other?
- What maximum size should we choose for stacks?
 - 8KB for **kernel-level** stacks in Linux on x86
 - Less need for tight space constraint for user-level stacks
- What happens if threads violate this?
 - "... program termination and/or corrupted data"
- How might you catch violations?
 - Place guard values at top and bottom of each stack
 - Check values on every context switch

Multiprogramming: Running Multiple Processes

Time Sharing

- **Illusion:** infinite number of processors
 - Each thread runs on dedicated virtual processor
- **Reality:** few processors, multiple threads running at variable speed
- How can we give illusion of infinite number of processors?
 - Multiplex in time!
- How do we **switch** from one process to next?
 - Save PC, SP, and registers in current PCB
 - Load PC, SP, and registers from new PCB
- What **triggers** switch?
 - Timer, voluntary yield, I/O interrupts, ...

How Do We Multiplex Processes?

- **Scheduling:** OS decides which process uses CPU time
 - Only one process is “running” on each CPU at any time
 - Scheduler could give more time to *important* processes
- **Protection:** OS divides non-CPU resources among processes
 - E.g., give each process their own address space
 - E.g., multiplex I/O through system calls

Scheduling

- Kernel scheduler decides which processes/threads receive CPU
- There are variety of scheduling policies for ...
 - Fairness or
 - Realtime guarantees or
 - Latency optimization or ...
- Kernel scheduler maintains data structure containing PCBs

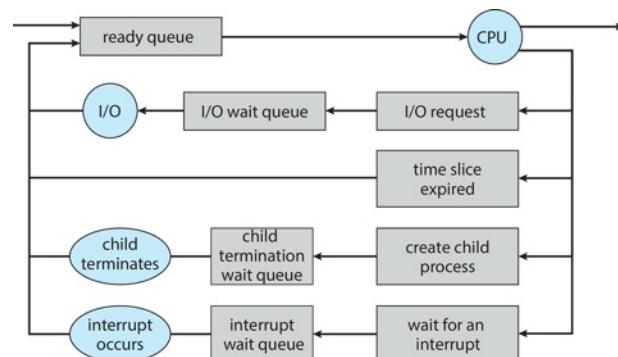

```
if (readyProcesses(PCBs)) {  
    nextPCB = selectProcess(PCBs);  
    run(nextPCB);  
} else {  
    run_idle_process();  
}
```

Ready Queue

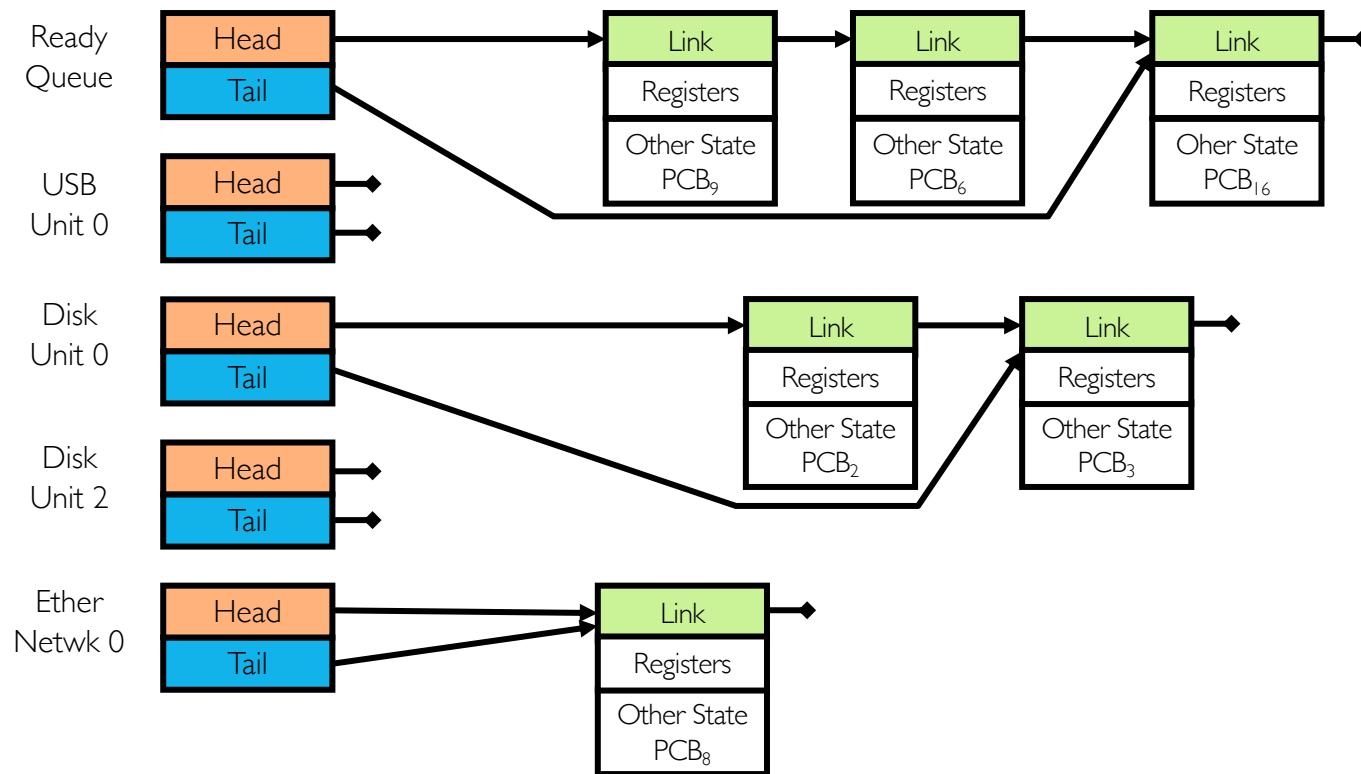

- PCBs move from queue to queue as they change state
 - Decisions about which order to remove from queues are **scheduling** decisions
 - Many algorithms possible (more on this in a few weeks)

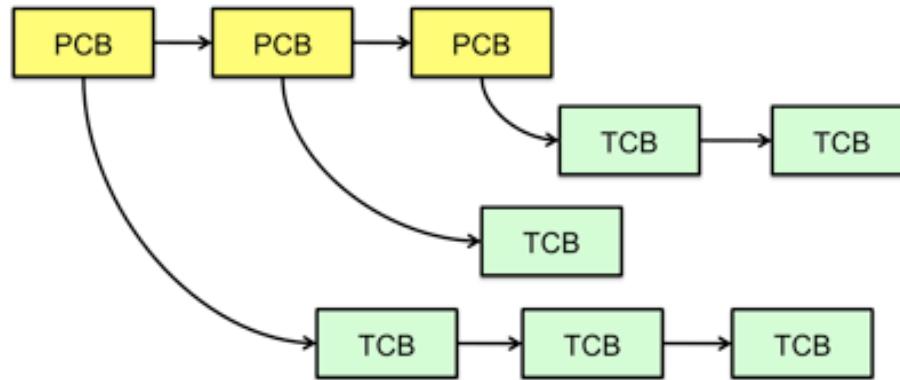

Ready Queue And I/O Device Queues

- Process not running \Rightarrow PCB is in some scheduler queue
 - Separate queue for each device/signal/condition
 - Each queue can have different scheduler policy

Multithreaded Processes

- PCBs could point to multiple TCBs

- Switching threads within one block is simple thread switch
- Switching threads across blocks requires changes to memory and I/O address tables

Protection

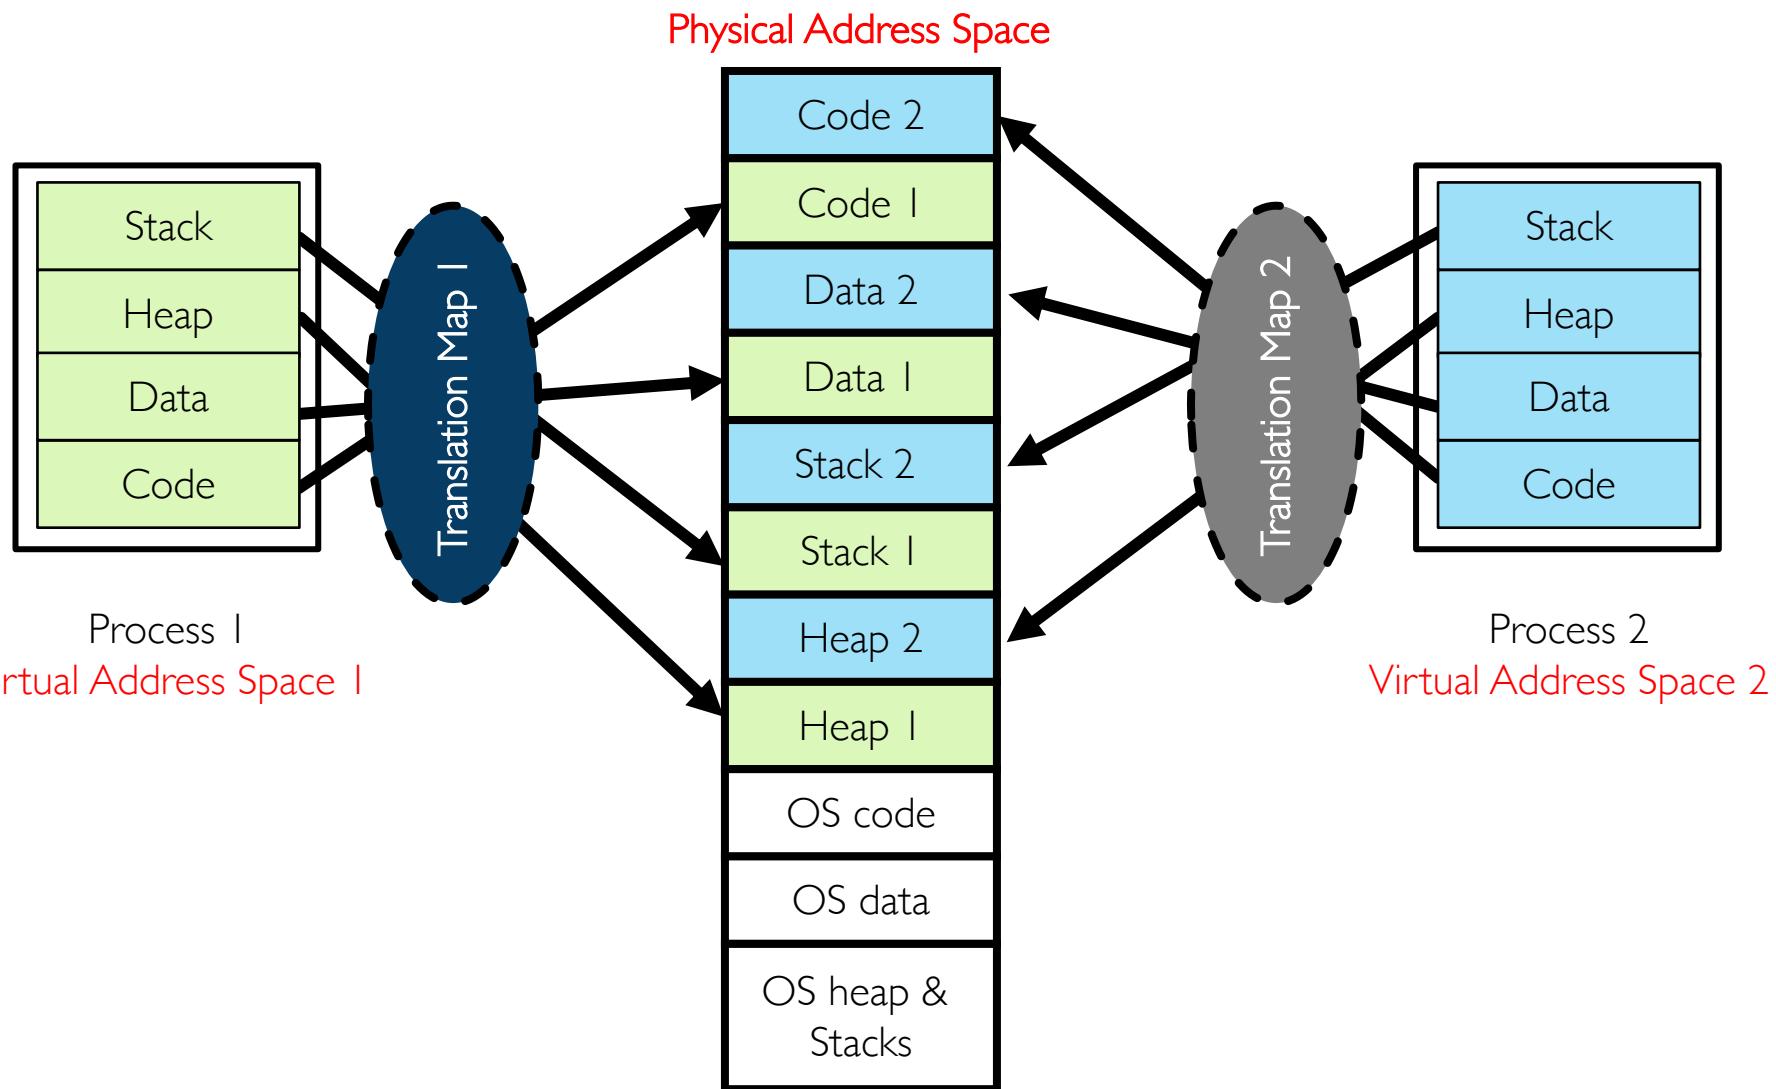

- OS must protect itself from user programs
 - Reliability: prevent OS from crashing
 - Security: limit scope of what processes can do
 - Privacy: limit data each process can access
 - Fairness: enforce appropriate share of HW
- It must protect user programs from one another
- Main method is to limit translation from virtual to physical address space

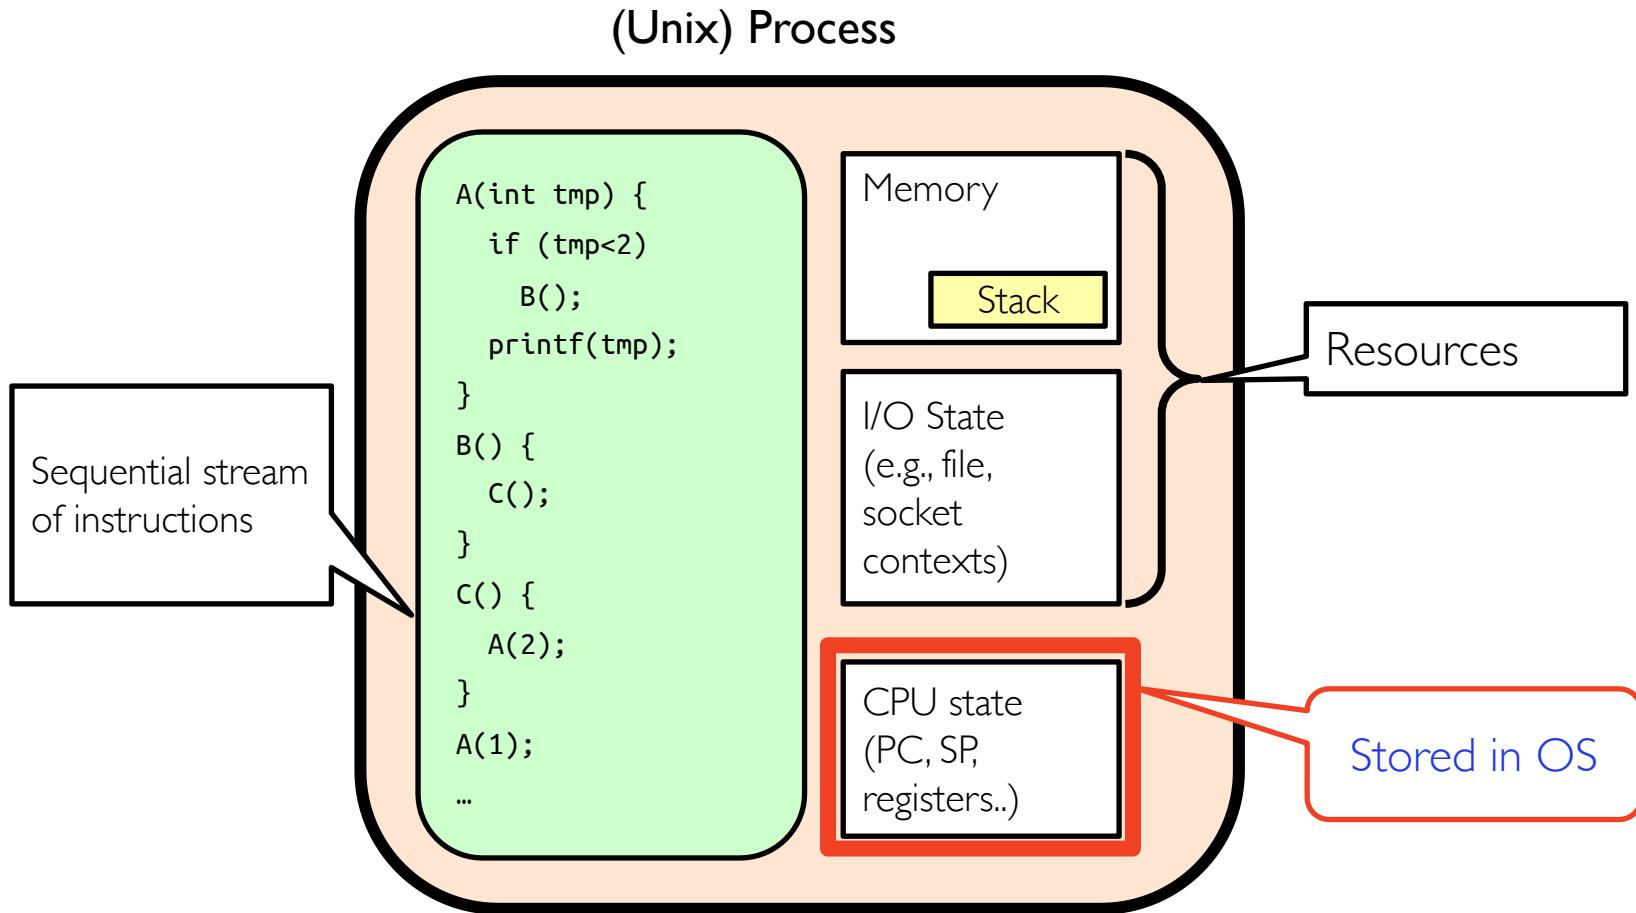

How to Protect Processes from One Another?

- Protection of **memory**
 - Every process does not have access to all memory
- Protection of **I/O devices**
 - Every process does not have access to every device
- Protection of access to **processor**
 - **Preemptive** switching from process to process
 - Use of **timer**
 - Must not be possible to disable timer from user code

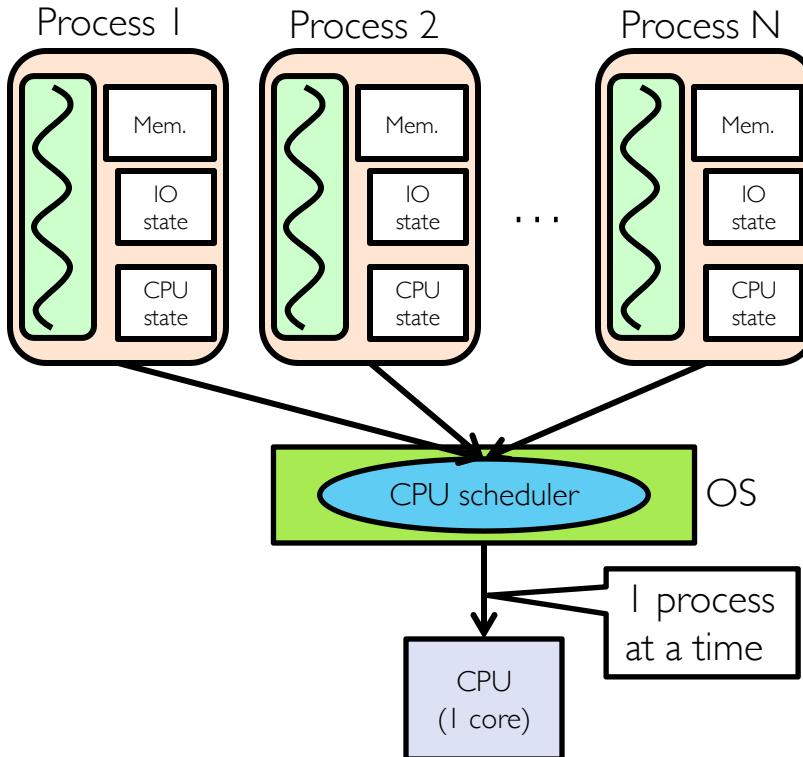

Address Translation Maps: Illusion of Separate Address Space

Putting it Together: Process

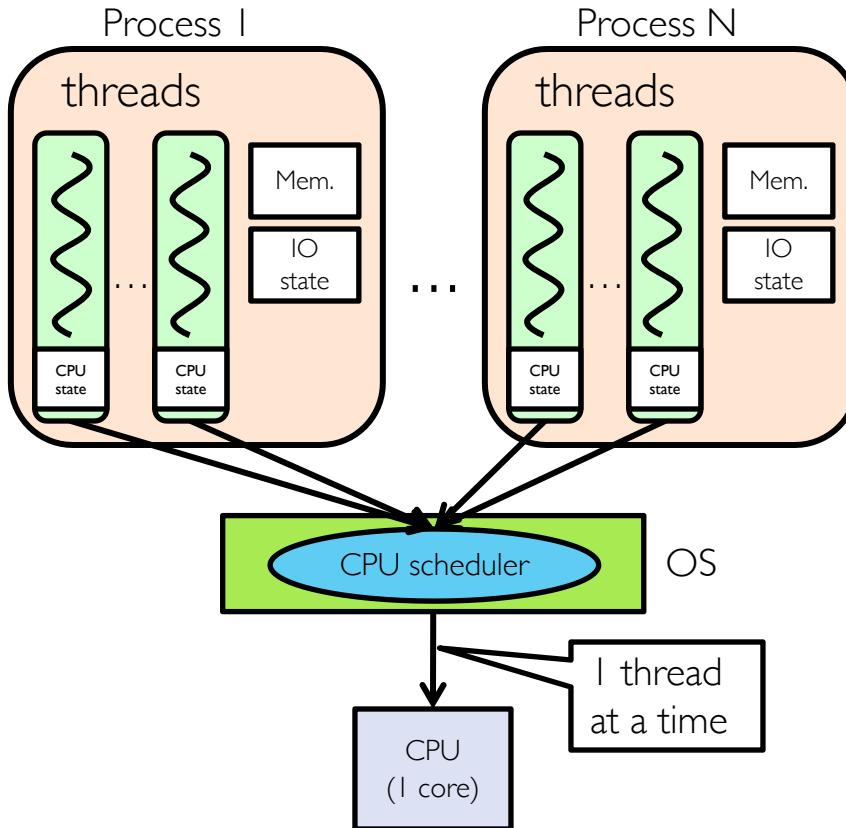

Putting it Together: Processes

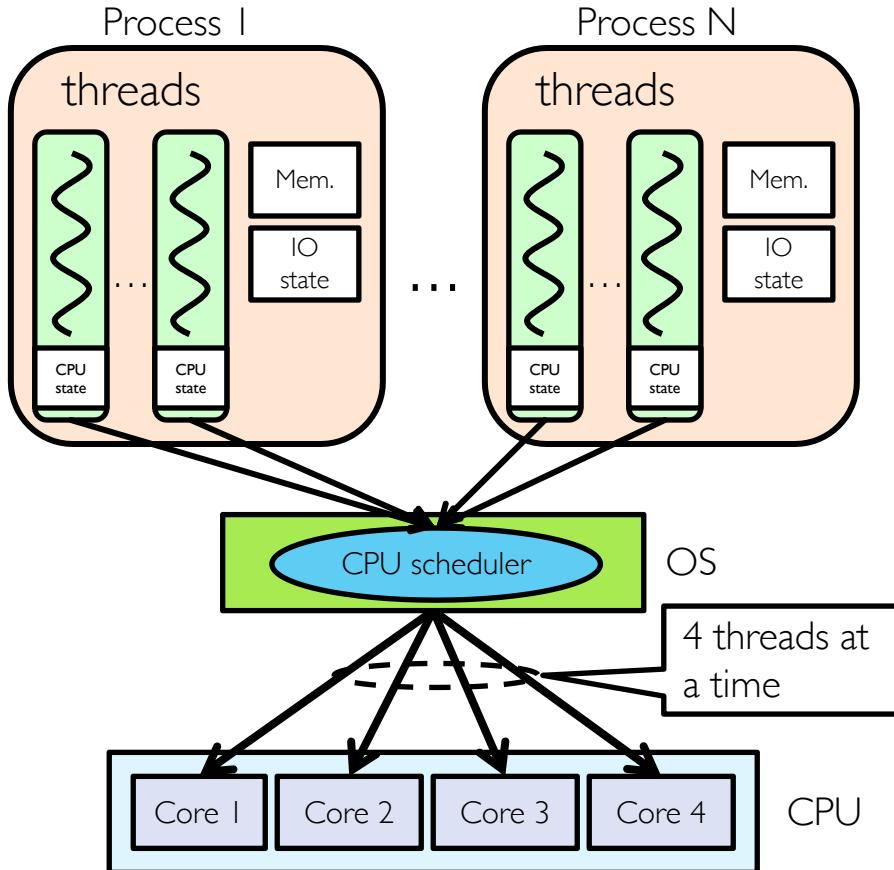

- Switch overhead: **high**
 - CPU state: **low**
 - Memory/IO state: **high**
- Process creation: **high**
- Protection
 - CPU: **yes**
 - Memory/IO: **yes**
- Sharing overhead: **high**
(involves at least one context switch)

Putting it Together: Threads

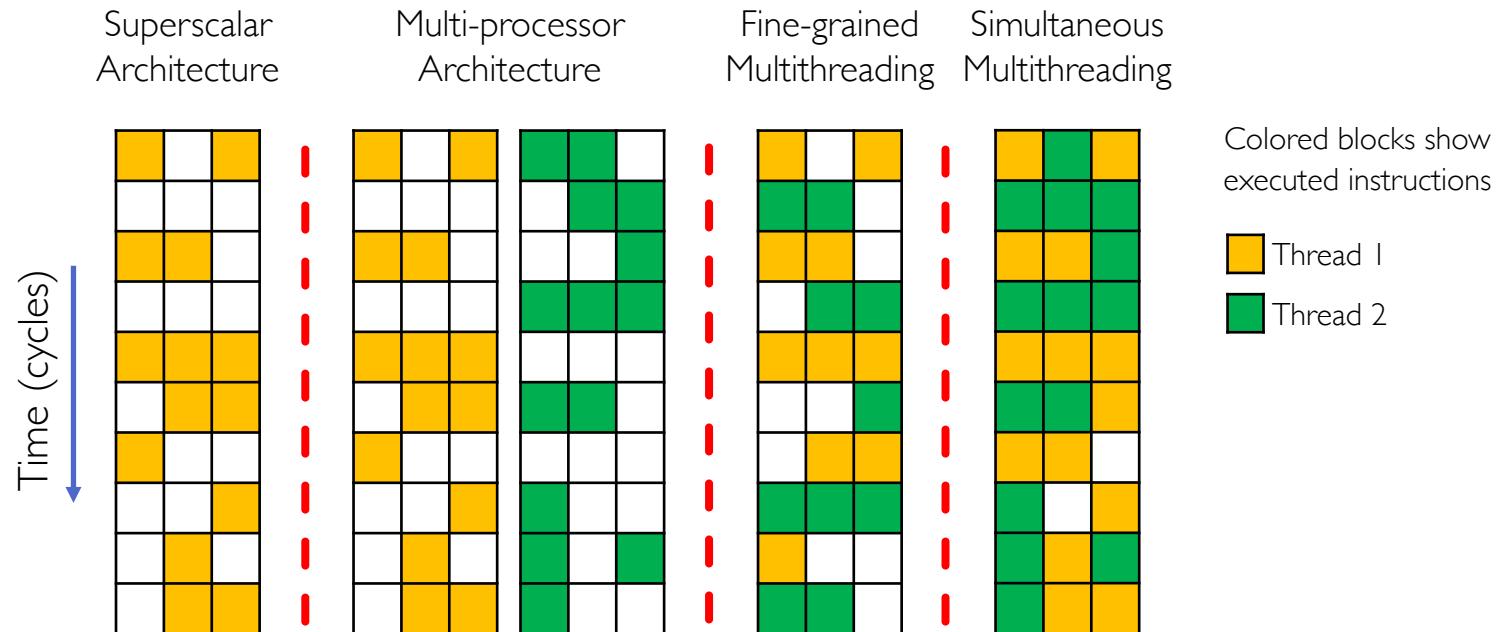

- Switch overhead: **medium**
 - CPU state: **low**
- Thread creation: **medium**
- Protection
 - CPU: **yes**
 - Memory/IO: **no**
- Sharing overhead: **low(ish)**
(thread switch overhead low)

Putting it Together: Multi-cores

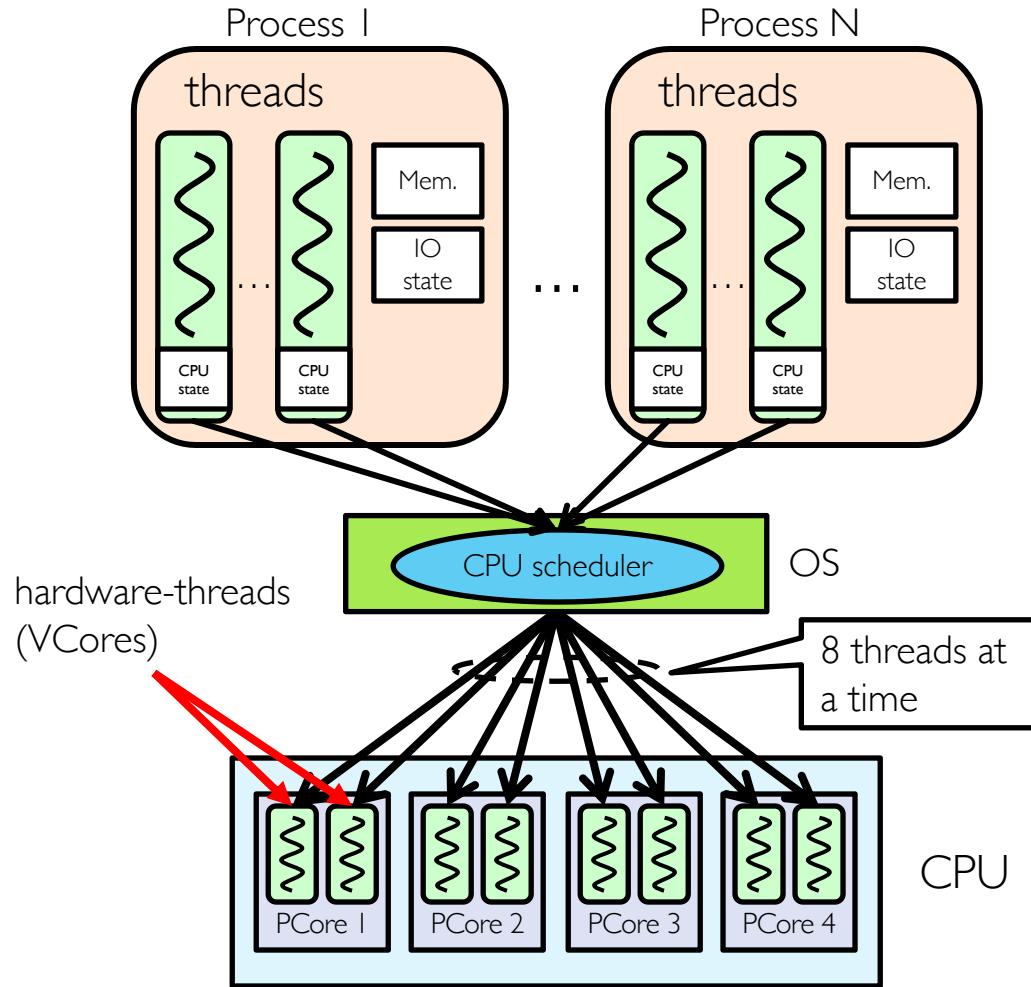

- Switch overhead: **low** (only CPU state)
- Thread creation: **low**
- Protection
 - CPU: **yes**
 - Memory/IO: **no**
- Sharing overhead: **low** (thread switch overhead **low**, may not need to switch at all!)

Hyperthreading

- Superscalar processors can execute multiple instructions that are independent
- Multiprocessors can execute multiple independent threads
- Fine-grained multithreading executes two independent threads by switches between them
- Hyperthreading duplicates register state to make second (hardware) “thread” (virtual core)
 - From OS’s point of view, virtual cores are separate CPUs
 - OS can schedule as many threads at a time as there are virtual cores (but, sub-linear speedup!)
 - See: <http://www.cs.washington.edu/research/smt/index.html>

Putting it Together: Hyperthreading

- Switch overhead between hardware-threads: **very-low** (done in hardware)
- Contention for ALUs/FPUs may **hurt** performance

Dual-mode Operation (4th OS Concept)

- Hardware provides at least two modes
 - Kernel mode (or “supervisor” or “protected”)
 - User mode, which is how normal programs are executed
- How can hardware support dual-mode operation?
 - Single bit of state (user/system mode bit)
 - Certain operations/actions only permitted in system/kernel mode
 - In user mode they fail or trap
 - User to kernel transition sets system mode AND saves user PC
 - OS code carefully puts aside user state then performs necessary actions
 - Kernel to user transition clears system mode AND restores user PC
 - E.g., `rfi`: return-from-interrupt

Three Types of Mode Transfer

- **System call**: request for kernel services
 - E.g., **open**, **close**, **read**, **write**, **lseek**
 - Usually implemented by calling *trap* or *syscall* instruction
 - Special instruction is not strictly required; on some systems, processes trigger system calls by executing some instruction with specific invalid opcode
- **Processor exception**: internal, *synchronous*, hardware event
 - E.g., divide by zero, illegal instruction, segmentation fault, page fault
 - Caused by software behavior
- **Interrupt**: external *asynchronous* event
 - E.g., timer, disk ready, network
 - Interrupts can be disabled, exceptions and traps cannot!

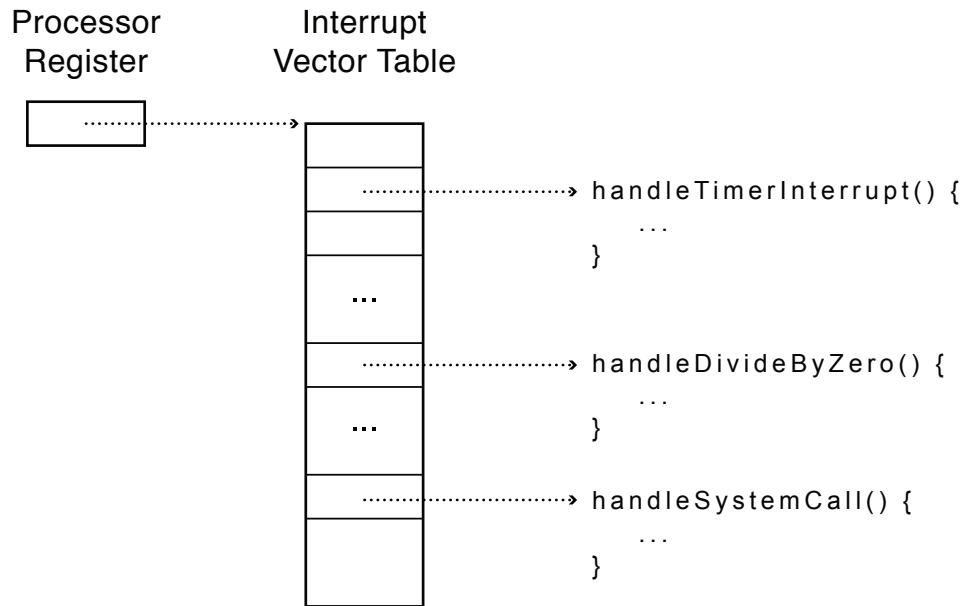

Interrupt Masking

- Interrupt handler runs with interrupts off
 - Re-enabled when interrupt completes
- kernel can also turn interrupts off
 - E.g., when determining next process/thread to run
 - On x86, `cli` disables interrupts and `sti` enables interrupts
 - Only applies to current CPU (on a multicore)
- We will need this to implement synchronization
(more on this later)

Implementing Safe Mode Transfers

- On system call, exception, or interrupt
 - Hardware enters kernel mode with interrupts disabled
 - Saves PC, then jumps to appropriate handler in kernel
 - Some processors (e.g., x86) also save registers, changes stack, etc.
- Actual handler typically saves registers, other CPU state, and switches to kernel stack (more on this soon)

Interrupt Vector Table

- Table set up by OS pointing to code to run on system calls, processor exceptions, and interrupts,

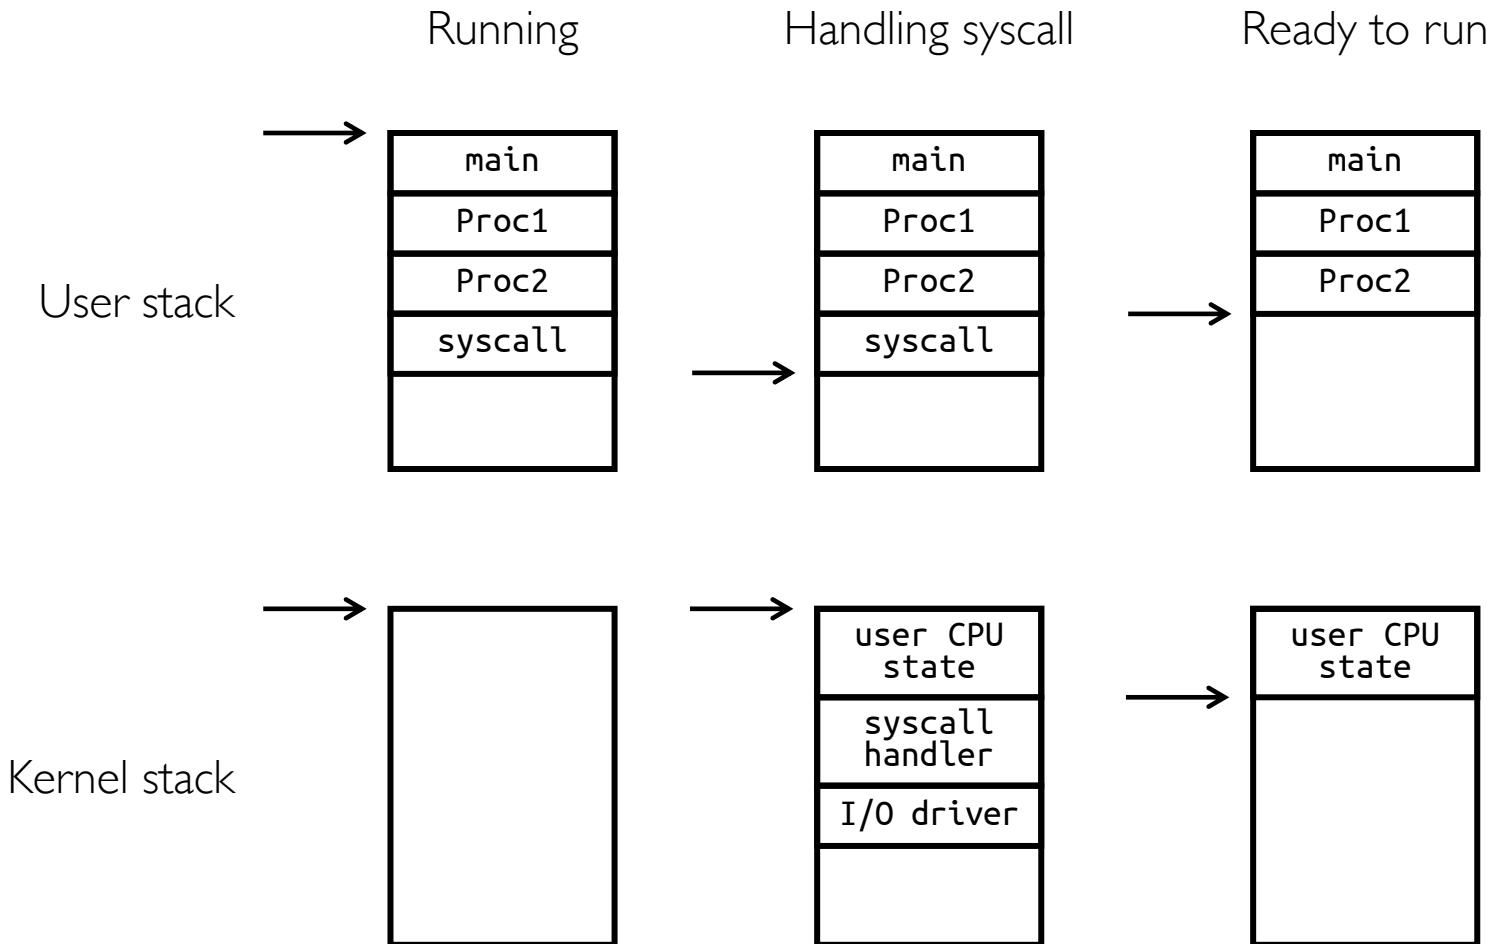

Implementing Safe Mode Transfers

- It should be impossible for buggy or malicious user program to cause kernel to corrupt itself
 - Controlled transfer into kernel (e.g., interrupt vector table)
 - Separate kernel stack
- Carefully constructed kernel code should pack up user process state and set it aside
 - Details depend on the machine architecture

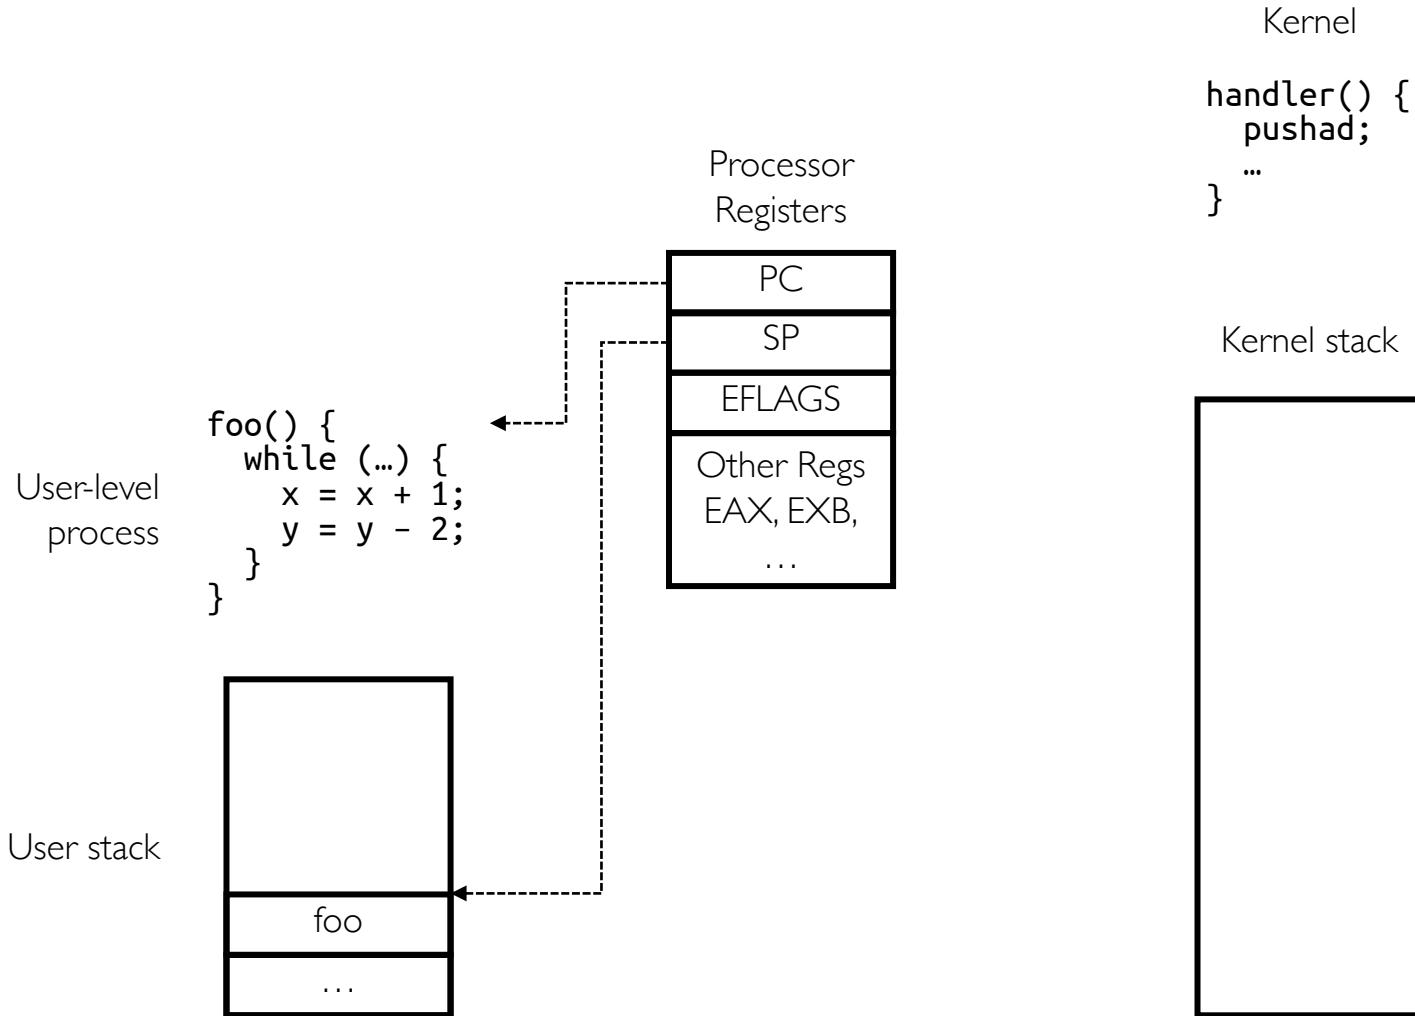

Need for Separate Kernel Stacks

- Kernel cannot put anything on user stack (Why?)
 - Reliability: what if user program's SP is not valid?
 - Security: what if other threads in user process change kernel's return address?
- Two-stack model
 - Kernel keeps separate stack for each thread in kernel memory (in addition to user stack in user memory)

Two-Stack Model

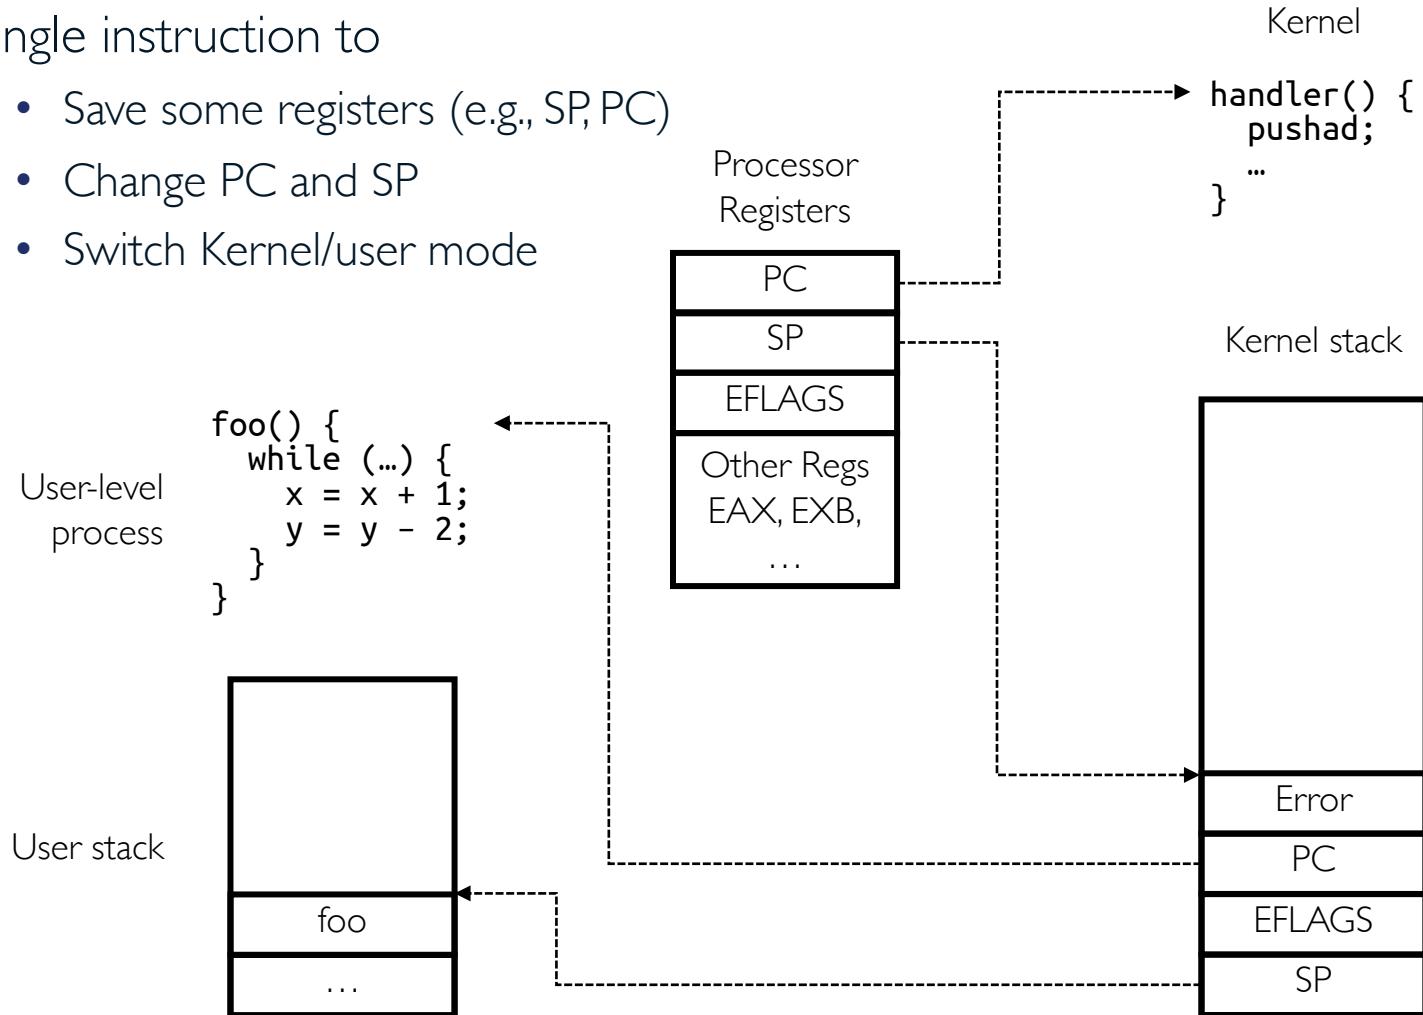

x86 Atomic Transfer of Control

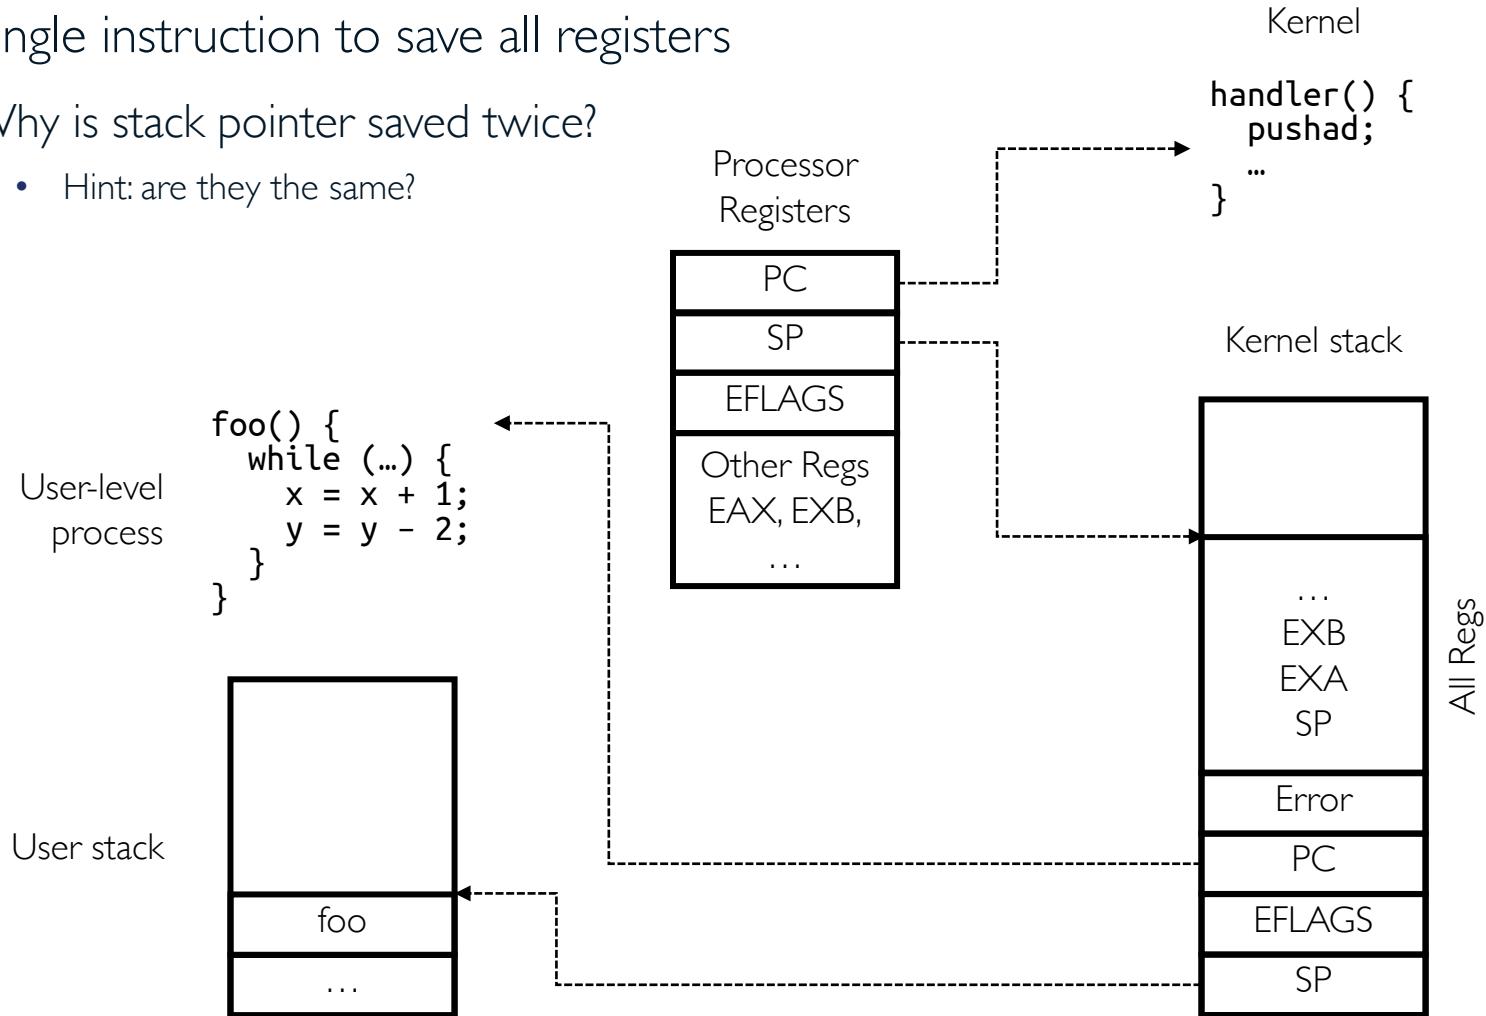

x86 Atomic Transfer of Control (cont.)

- Single instruction to
 - Save some registers (e.g., SP, PC)
 - Change PC and SP
 - Switch Kernel/user mode

x86 Atomic Transfer of Control (cont.)

- Single instruction to save all registers
- Why is stack pointer saved twice?
 - Hint: are they the same?

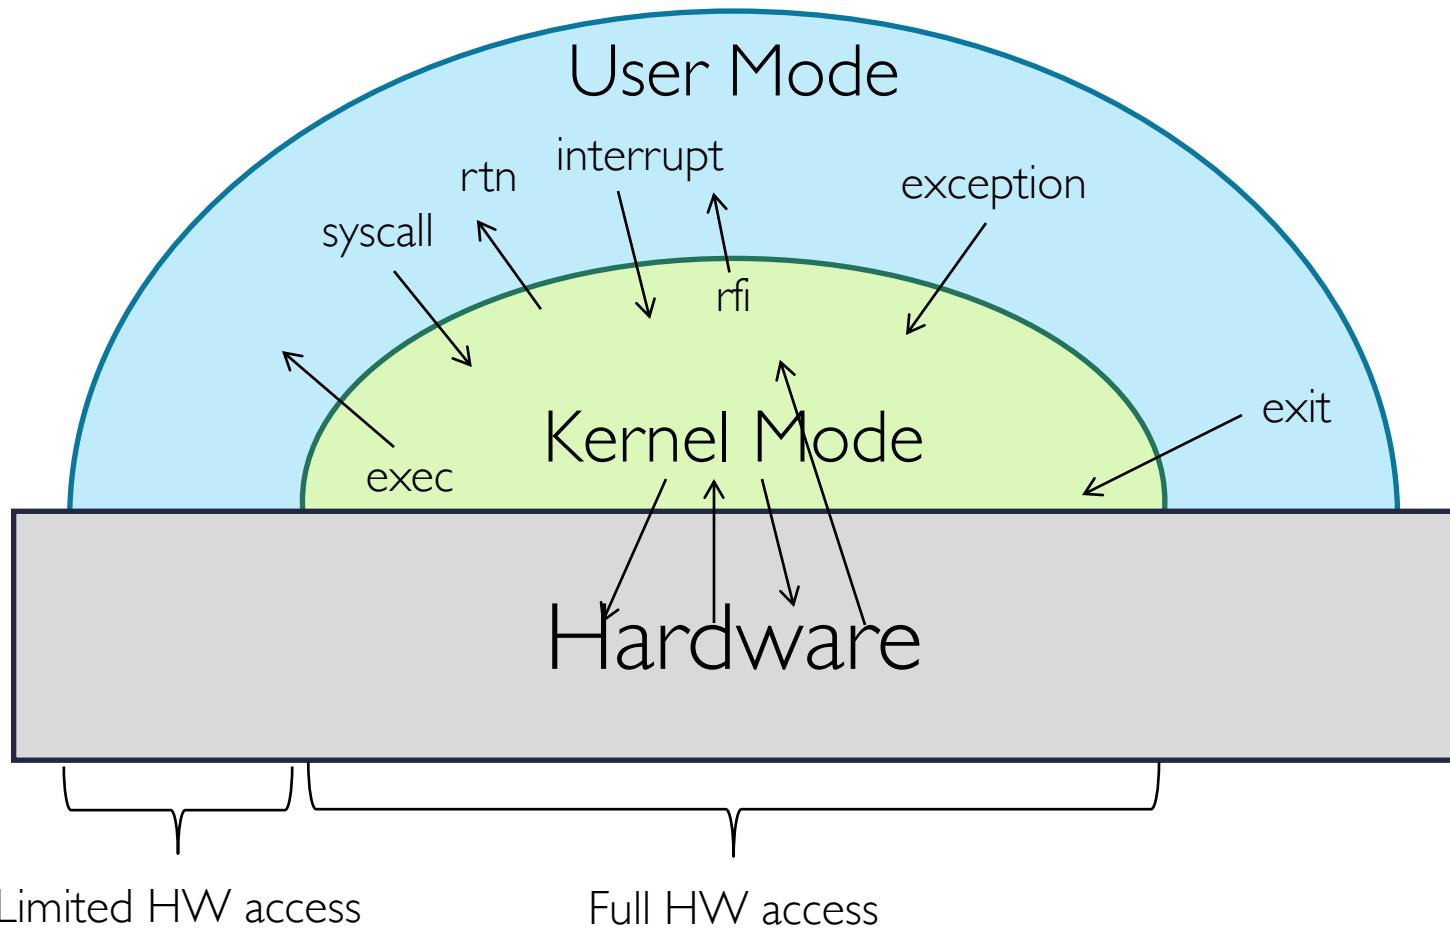

Example: System Call Handler

- Vector through well-defined system call entry points!
 - Table mapping system call number to handler
- Locate arguments
 - In registers or on user (!) stack
- Copy arguments (copy before check)
 - From user memory into kernel memory
 - Protect kernel from malicious code evading checks
- Validate arguments
 - Protect kernel from errors in user code
- Copy results back
 - Into user memory

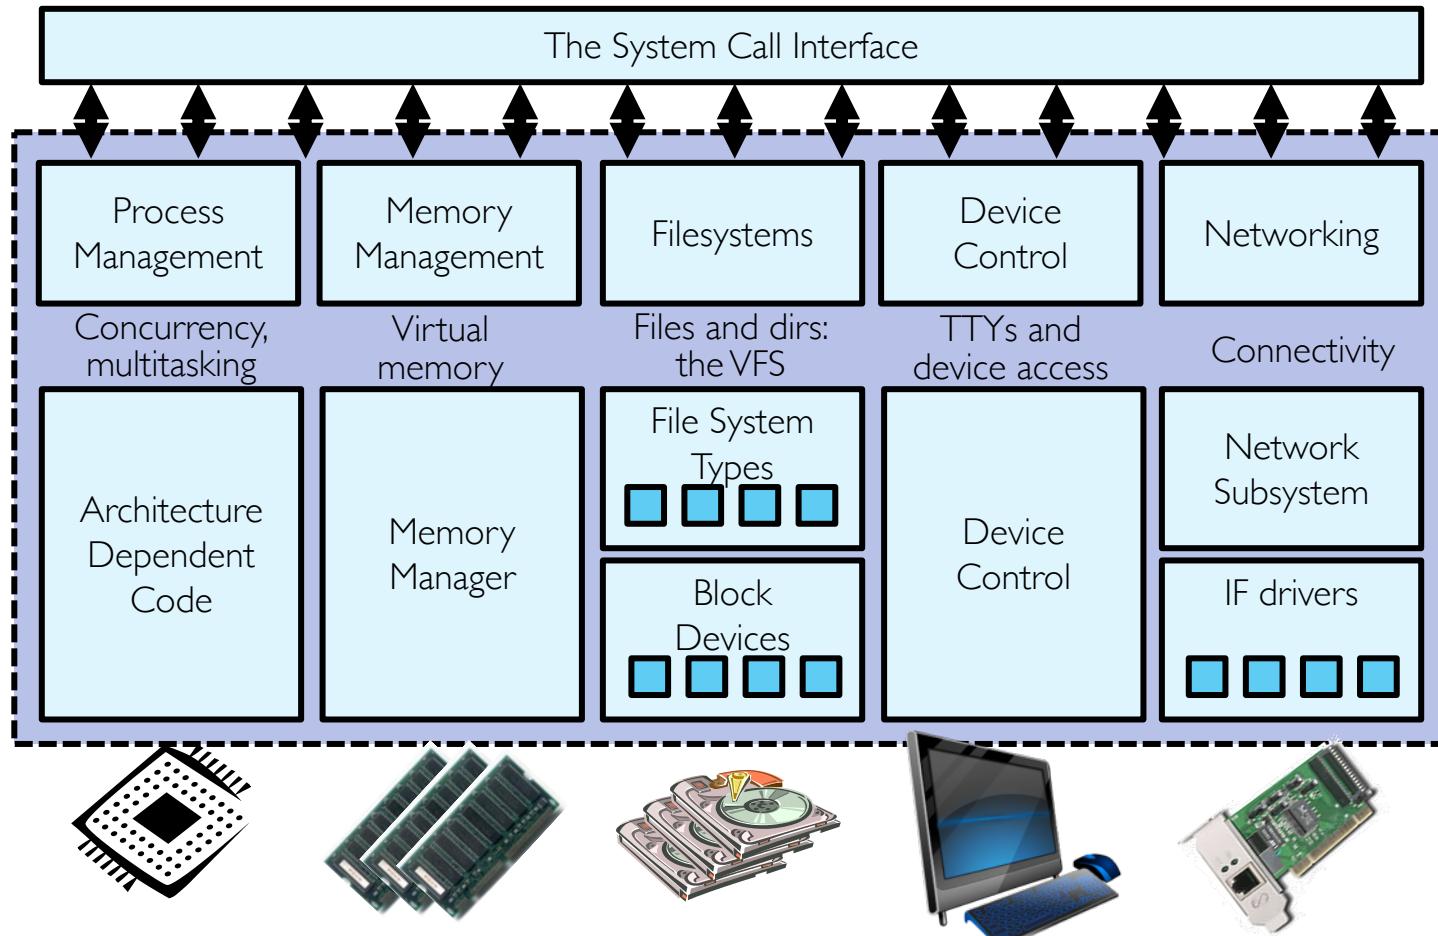

Kernel to User Mode Switch

- New process/new thread start
 - Jump to first instruction in program/thread
- Return from interrupt, exception, system call
 - Resume suspended execution
- Process/thread context switch
 - Resume some other process
- User-level *upcall* (UNIX *signal*)
 - Asynchronous notification to user program
 - Preemptive user-level threads
 - Asynchronous I/O notification
 - Interprocess communication
 - User-level exception handling
 - User-level resource allocation

Example: User/Kernel Mode Transfers

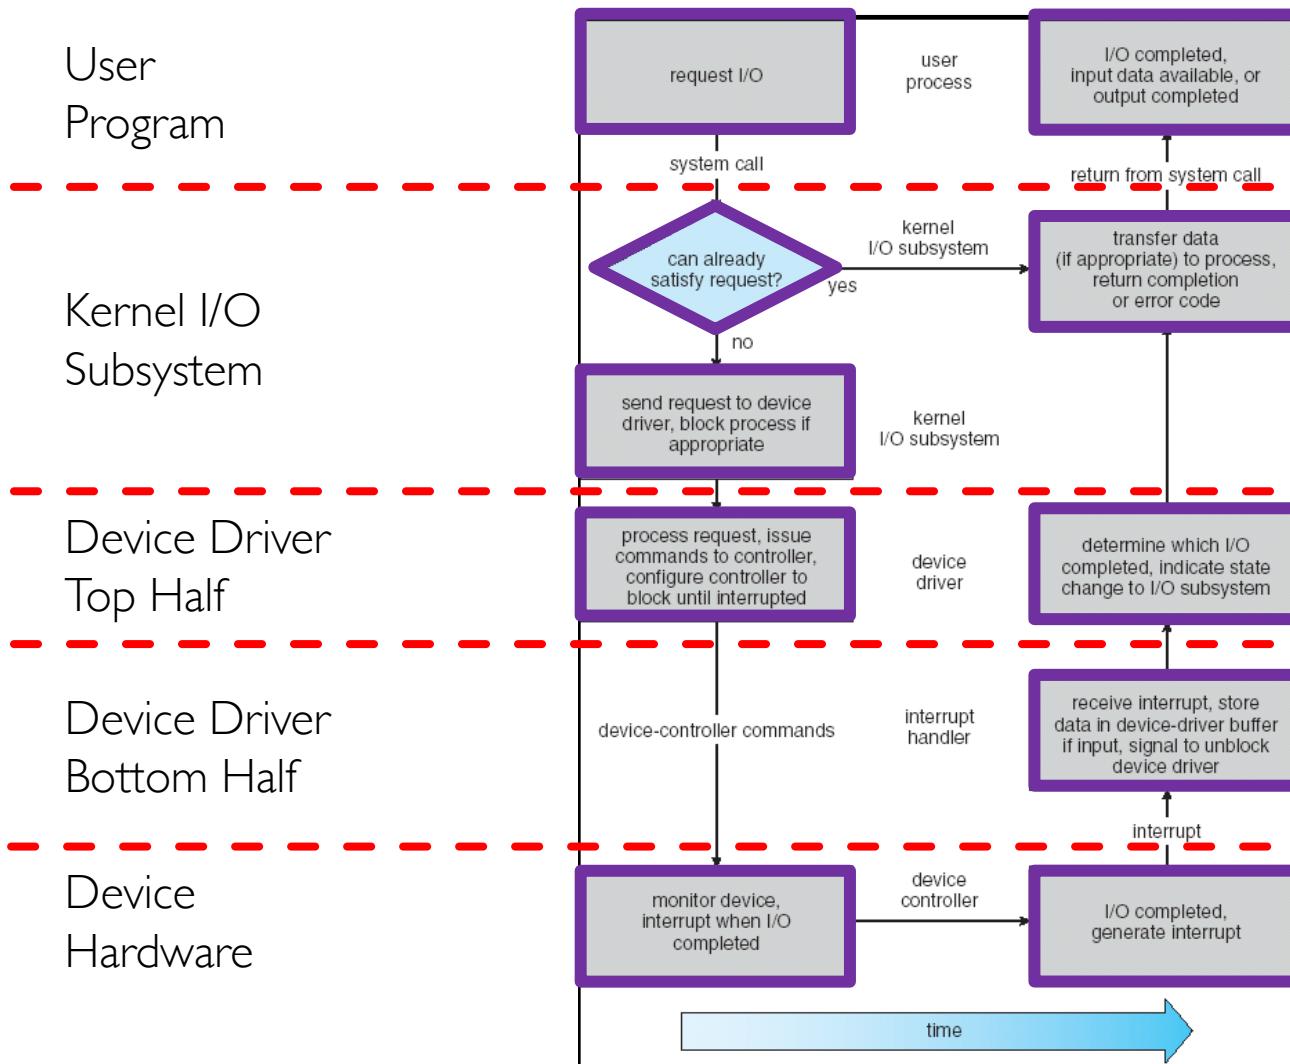

System Call Interface: Access Point to Hardware Resources

Device Drivers

- Device-specific code in kernel that interacts directly with device hardware
 - Supports standard, internal interface
 - Same kernel I/O system can interact easily with different device drivers
 - Special device-specific configuration supported with `ioctl()` syscall
- Device drivers are typically divided into two pieces
 - Top half: accessed in call path from system calls
 - implements a set of standard, cross-device calls like `open()`, `close()`, `read()`, `write()`, `ioctl()`, etc.
 - This is kernel's interface to device driver
 - Top half will start I/O to device, may put thread to sleep until finished
 - Bottom half: run as interrupt routine
 - Gets input or transfers next block of output
 - May wake sleeping threads if I/O now complete

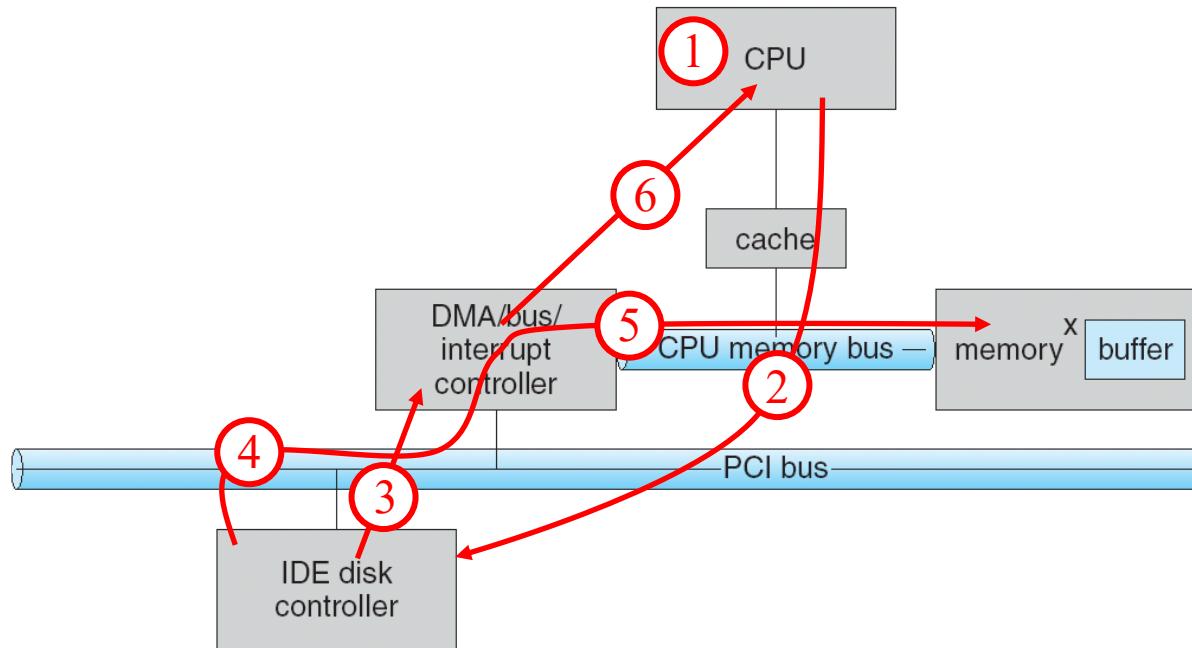

Life Cycle of an I/O Request

I/O Data Transfer

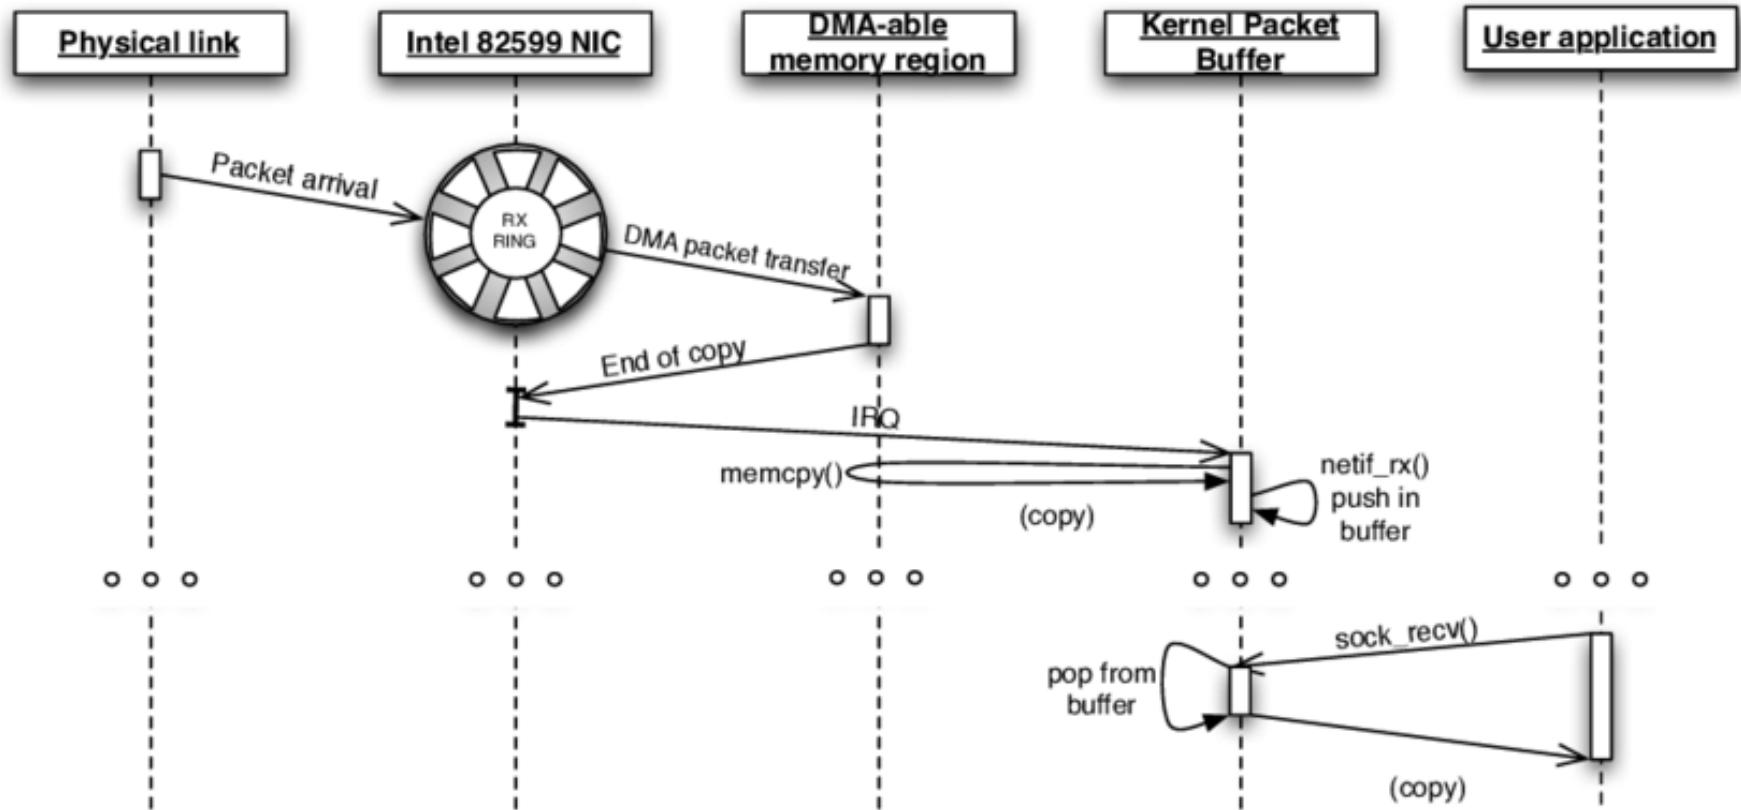

- Programmed I/O
 - Each byte transferred via processor in/out or load/store
 - + Simple hardware, easy to program
 - – Consumes processor cycles proportional to data size
- Direct memory access (DMA)
 - Give controller access to memory bus
 - Ask it to transfer data blocks to/from memory directly

DMA Transfer

1. Device driver is told to transfer disk data to buffer at address x
2. Device driver tells disk controller to transfer C bytes from disk to buffer at address x
3. Disk controller initiates DMA transfer
4. Disk controller send each byte to DMA controller
5. DMA controller transfers bytes to buffer x , increasing address and decreasing C
6. When $C = 0$, DMA interrupts CPU to signal transfer completion

DMA Example: Network Stack in Linux Kernels before 2.6

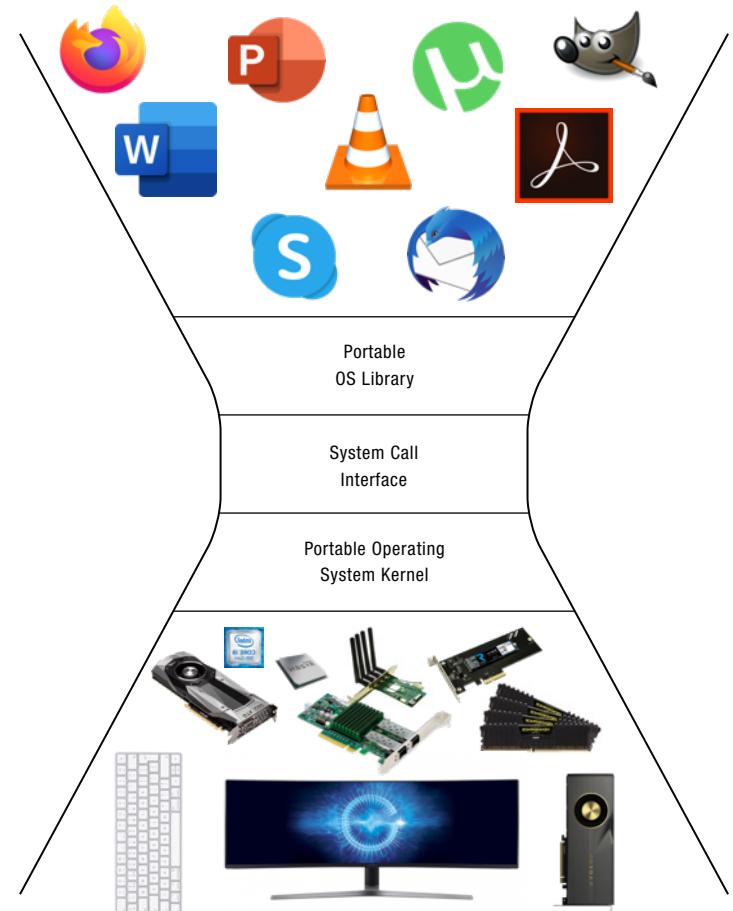

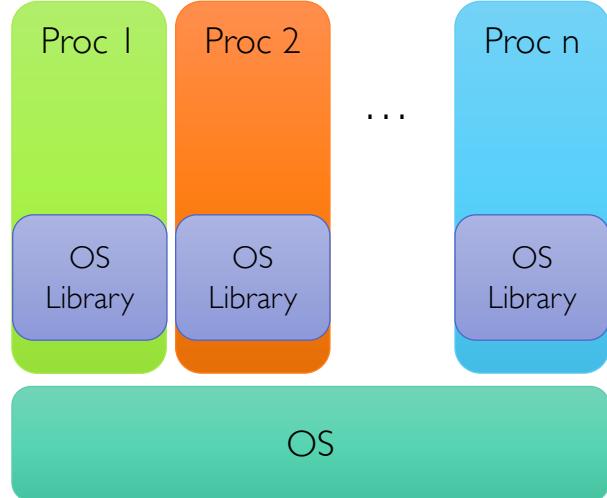

How Does Kernel Provide Services?

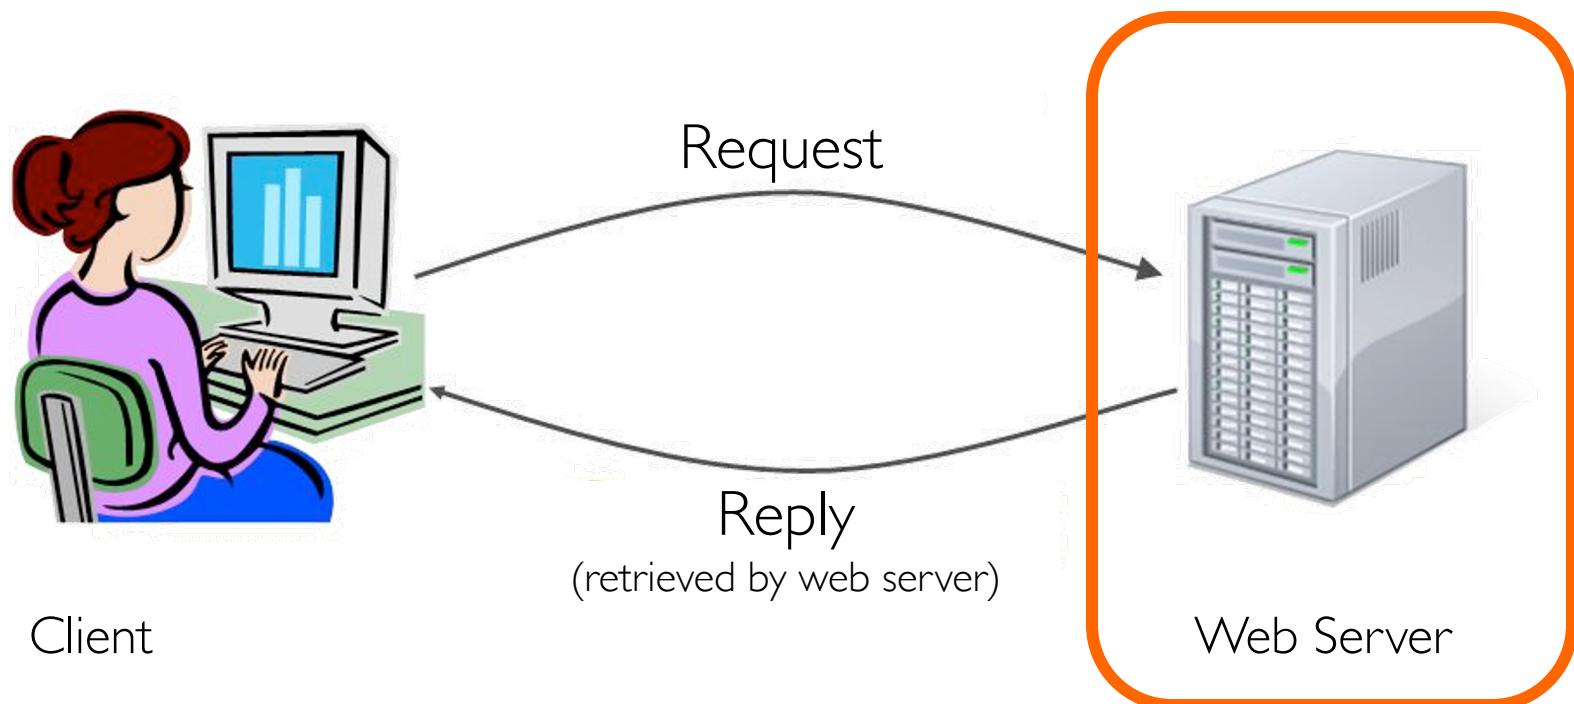

- You said that applications request services from OS via syscall, but ...
 - I've been writing all sorts of applications, and I never ever saw a "syscall" !!!
- That's right!
- It was buried in the programming language runtime library (e.g., libc.a)
 - ... Layering

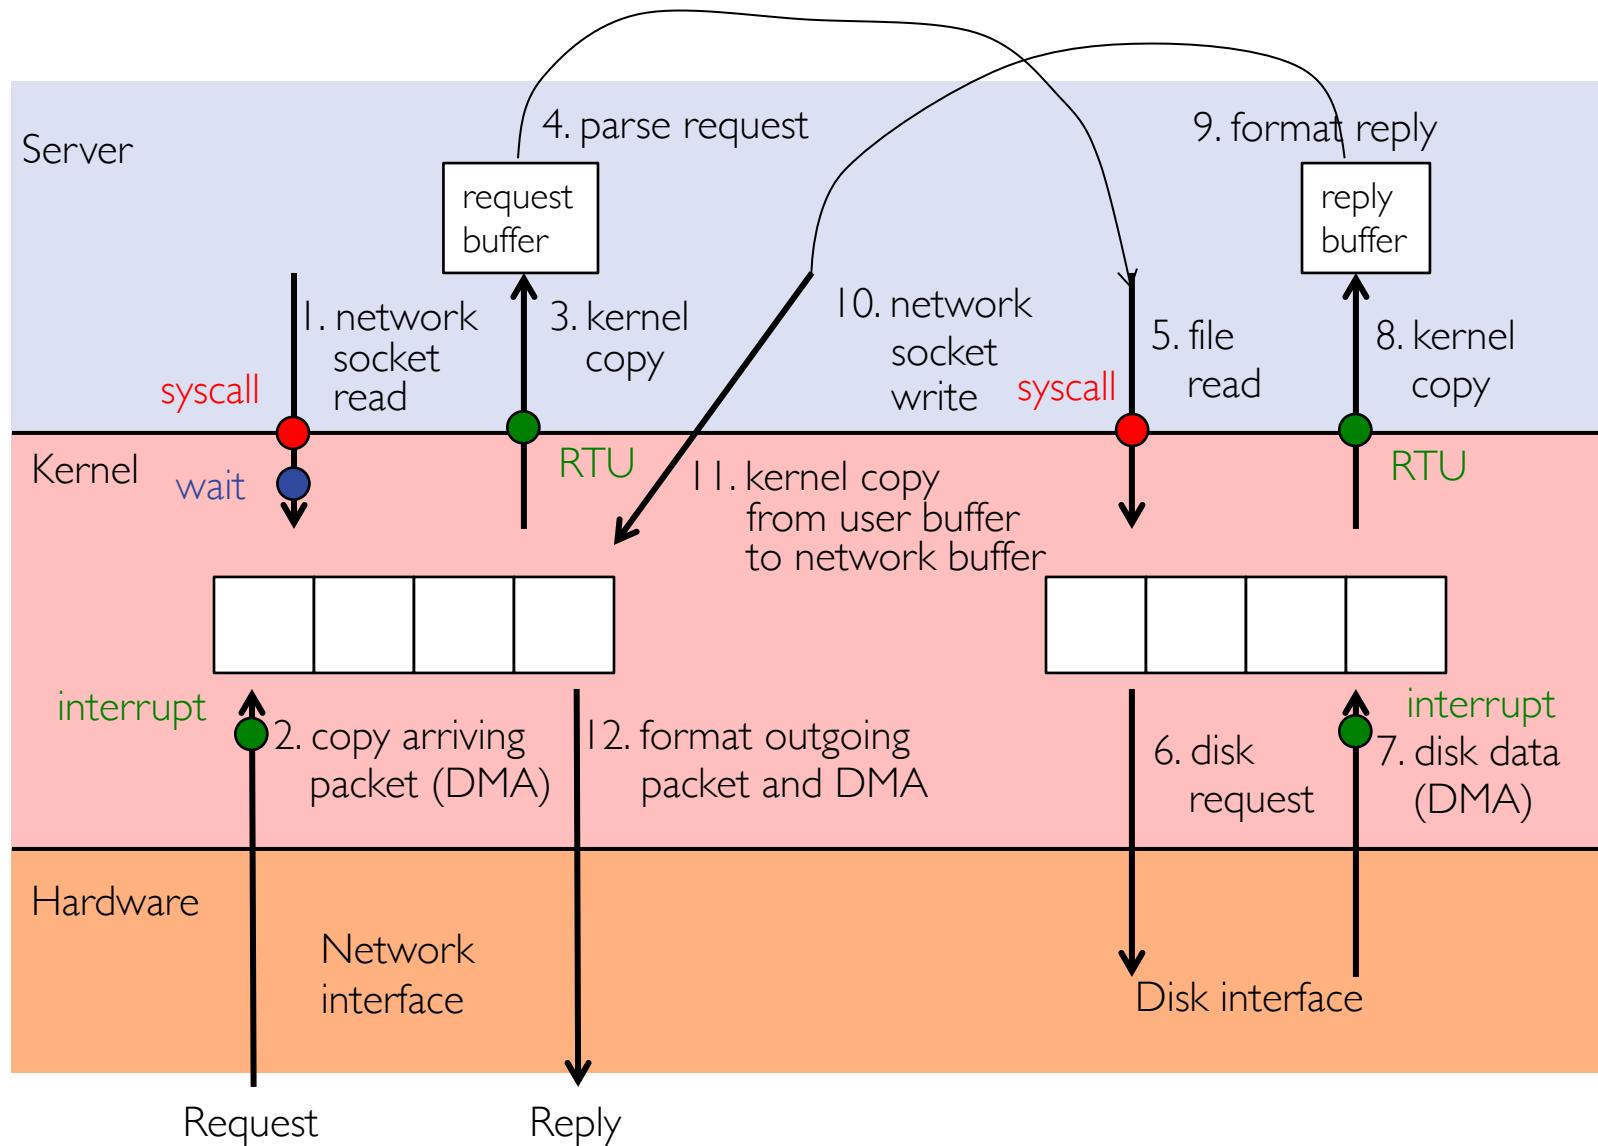

OS Run-time Library

Putting it Together: Web Server

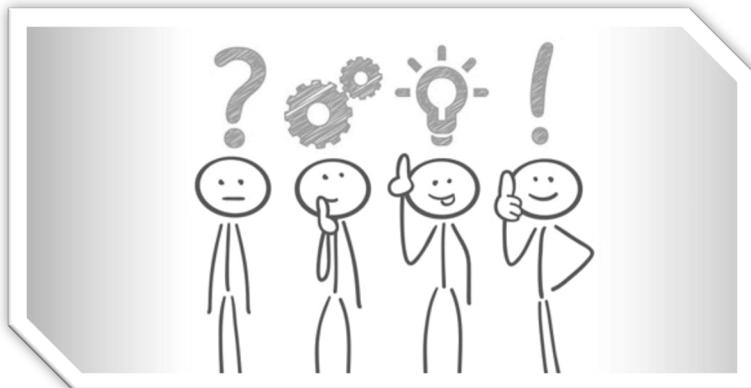

Putting it Together: Web Server (cont.)

Summary

- Thread
 - Single unique execution context which fully describes program state
 - Program counter, registers, execution flags, stack
- Address space (with translation)
 - Address space which is distinct from machine's physical memory addresses
- Process
 - Instance of executing program consisting of address space and 1+ threads
- Dual-mode operation/protection
 - Only "system" can access certain resources
 - OS and hardware are protected from user programs
 - User programs are isolated from one another by controlling translation from program virtual addresses to machine physical addresses
